20. ABSTRACT (Continue on reverse side if necessary and identify by block number)  The multiple precision approach paths which are possible with microwave landing systems pose new lateral separation problems for the simultaneous optimum curved approach trajectories. Separation criteria for these new multiple paths will be influenced by aircraft path tracking performance. Manually piloted STOL aircraft will be particularly sensitive to atmospheric turbulence during precision tracking.

In this study a parametric variation of the open loop poles of a STOL aircraft was made using stability augmentation system (SAS) gains, and the gust response of the manually piloted aircraft was analyzed at points on an MLS approach path. The study was reduced to two quadratic optimal control problems for linear infinite time stochastic systems: (1) to compute the SAS gains using a rate-model-in-the-performance-index pole placement algorithm, and (2) to calculate the pilot gains and system gust response using a quadratic optimal pilot model. Both the SAS and pilot gains calculation yielded reasonable low gains for all cases, and the four lateral-directional poles and the longitudinal short period poles could be placed accurately.

The rms vertical path error in severe turbulence was smallest for the unaugmented poles, except for the final approach at 60 knots where the unconstrained control motions are airspeed response slightly exceeded physical limits for all SAS designs considered in this study.

The rms lateral path error was an order of magnitude larger than the vertical error, and SAS pole variation caused a significant plus and minus 50 percent variation in this error. The lateral error increased with dutch roll frequency and damping and decreased with spiral and roll stability. The most significant improvement in lateral error was achieved by increasing roll stability. The variation in lateral path error with bank angle was also significant and the nature of the variation was strongly influenced by the specific augmented poles. There was a conflict between good conventional flying qualities and optimum gust response since increased dutch roll frequency yielded the greatest reduction in the objectionable lateral and directional mode cross coupling while increasing the lateral gust response error.

FOREWORD

This report was originally prepared as a thesis by Major Milton B. Porter, Jr., in partial fulfillment of the requirements for the degree of Doctor of Philosophy from Purdue University, Lafayette, Indiana. Maj Porter's thesis advisor was Professor Robert L. Swaim, PhD.

The research was completed while the author was assigned to the Terminal Area Control Branch, Flight Control Division, Air Force Flight Dynamics Laboratory, Wright-Patterson Air Force Base, Ohio. The research was initiated at Purdue University, continued under Project 8219, and completed under Project 1986, Task 198602, Work Unit 19860203.

The research was conducted during the period of June 1971 to May 1975.

## LIST OF SYMBOLS

A	Matrix of state variable coefficients
$A_{\underline{u}}, A_p, \dots$	A-matrix column of coefficients of $\underline{u}, p, \dots$
$a_{ij}$	ijth element of A-matrix
b	Wing span
B	Matrix of control variable coefficients
$C, C_1, C_2$	Matrices of state variable coefficients for observation vector
$C_D$	Drag coefficient
$\bar{C}_D$	Drag coefficient including thrust
$C_L$	Lift coefficient
$C_{l_p}, C_{n_p}$	Stability derivatives with respect to roll rate
$C_{l_r}, C_{n_r}$	Stability derivatives with respect to yaw rate
$C_{l_{r_g}}, C_{n_{r_g}}$	Stability derivatives with respect to the equivalent yaw gust velocity
$C_{l_\beta}, C_{n_\beta}, C_{Y_\beta}$	Stability derivatives with respect to sideslip (side velocity)
$C_{l_{\delta_a}}, C_{n_{\delta_a}}, C_{Y_{\delta_a}}$	Control derivatives with respect to aileron deflection
$C_{l_{\delta_r}}, C_{n_{\delta_r}}, C_{Y_{\delta_r}}$	Control derivatives with respect to rudder deflection
$C_{m_q}, C_{z_q}$	Stability derivatives with respect to pitch rate

# Contrails

$C_{m_u}, C_{x_u}, C_{z_u}$	Stability derivatives with respect to the forward velocity
$C_{m_\alpha}, C_{x_\alpha}, C_{z_\alpha}$	Stability derivatives with respect to the angle of attack (vertical velocity)
$C_{m_\dot{\alpha}}, C_{z_\dot{\alpha}}$	Stability derivatives with respect to the angle of attack rate
$C_{m_{\delta_e}}, C_{z_{\delta_e}}$	Control derivatives with respect to the elevator deflection
$C_{m_{\delta_T}}, C_{x_{\delta_T}}, C_{z_{\delta_T}}$	Control derivatives with respect to the throttle deflection
$c$	Mean aerodynamic chord
$cg$	Aircraft center of gravity
$c_p/\delta_T$	= 1200; scale factor for throttle control derivatives
$D$	Matrix of state variable coefficients for response vector
$d_x, d_y, d_z$	Displacement from the flight path
$\det()$	Determinant
$dB$	Decibel
$F$	Feedback state coefficient matrix
$F(x) = [0]$	Vector function equation for rate-model Newton-Raphson iteration
$F_x, F_y, F_z$	Total force components in the body stability axes
$F_{x_A}$	Aerodynamic force component along the x-stability axis
$F_{g_x}, F_{g_y}, F_{g_z}$	Gravitational force components in the body stability axes
$f_1, \dots, f_{13}, f_x, f_y, f_z$	Parameters in equations of motion
$g$	= 32.174 ft/sec <sup>2</sup> ; sea level reference acceleration of gravity

# Contrails

G	Matrix of stochastic variable coefficients
H	Matrix of system feedback gains to be optimized
h	Altitude above ground level
$I_n$	Identity matrix of order n
$I_{xx}, I_{yy}, I_{zz}$	Stability axes moments of inertia
$I_{xz}$	Stability axis product of inertia
J	Quadratic optimal performance function
K	System gain (with appropriate subscript)
$K_i$	Gain adjoint matrix
$K_p$	Pilot gain
$K_R$	Gain constant in pilot remnant
L, M, N	Total roll, pitch and yaw moments about the body stability axes
$L_u, L_v, L_w$	Gust scale lengths
$l_t$	Distance from aircraft cg to the center of pressure of the horizontal stabilizer
M, G	Matrix of stochastic variable coefficients
$M_T$	Pitching moment due to thrust change
MLS	Microwave Landing System
m	Aircraft mass
$n_{\delta_a}, n_{\delta_e}$	Stochastic variables for pilot aileron and elevator command remnant
$O_{n \times m}$	Zero matrix of order n by m
P	Engine power
P	State covariance matrix

# Contrails

$P, Q, R$	Total roll, pitch, and yaw rates about the body stability axes
$p, q, r$	Perturbation roll, pitch, and yaw rates about the body stability axes
$p_g, q_g, r_g$	Equivalent roll, pitch, and yaw gust velocities
$P_i$	Probability of $i$ th discrete event
$Q$	Quadratic optimal weighting matrix
$q_{x_p}, q_y, q_{u_p}$	Diagonal weighting elements for pilot gains calculation
$R^{n \times m}$	Space of real $n$ by $m$ matrices
$r$	Random variable, over the domain $\Omega_1$
rms	Root mean square (standard deviation for a zero mean variable)
$S$	Reference wing area
SAS	Stability augmentation system
$s$	Laplace domain variable
$T$	Propeller thrust
$T(j\omega)$	Spectral factor or transfer function
$T'_c$	Thrust coefficient
$T_{d_e}$	Effective dwell interval of the pilot's eye fixation
$T_I, T_l$	Pilot delay time constants
$T_L$	Pilot lead time constant
$T_R$	Roll mode time constant
$T_S$	Spiral mode time constant
$T_{1/2}$	Time-to-one-half amplitude
$U, V, W$	Components of total linear velocity along the body stability axes

# Contrails

$U_w, V_w, W_w$	Components of the deterministic wind velocity along the body stability axes
$u$	Vector of control variables
$u, v, w$	Components of perturbation linear velocity along the body stability axes
$\underline{u}$	Normalized perturbation velocity component along the x-stability axis
$\underline{u}_g, \alpha_g, \beta_g$	Normalized gust linear velocities along the body stability axes (equivalent gust longitudinal velocity, angle of attack, and sideslip)
$V_{con}$	Conventional/STOL conversion speed
$\bar{V}_w$	Deterministic wind velocity
$v_1$	Vector of pilot control inputs
$W$	Stochastic disturbance covariance matrix
$x$	(1) Denotes one axis of a cartesian (x, y, z) coordinate system (with appropriate subscript), or (2) denotes a state variable or vector of state variables
$x_{p1}, x_{p2}$	Pilot state variables
$x_1, x_2, x_3, x_4$	Solutions to rate-model Newton-Raphson iteration
$y$	Vector of observations of the system states
$z$	System response vector
$\alpha$	Perturbation angle of attack (normalized perturbation linear velocity component along the z-stability axis)
$\beta$	Perturbation sideslip angle (normalized perturbation linear velocity component along the y-stability axis)

# Contrails

$\beta(t, \omega)$	Wiener stochastic process
$\Gamma_0$	Nominal approach glideslope angle
$\delta_a, \delta_e, \delta_r, \delta_T$	Control deflection variables (aileron, elevator, rudder, throttle)
$\delta_p$	Pilot control command
$\Delta()$	Perturbation force or moment
$\epsilon$	(1) Arbitrarily small positive number, or (2) denotes that an element "belongs to" a set or space of elements
$\zeta$	Damping ratio
$\eta$	Vector of stochastic disturbance variables
$\eta_e$	Effective dwell fraction of the pilot's eye fixation
$\theta, \phi, \psi$	Euler total pitch, roll, and heading angles
$\theta, \phi, \psi$	Euler perturbation pitch, roll, and heading angles
$\sigma$	Standard deviation (rms value of a zero mean stochastic variable)
$\sigma_u, \sigma_v, \sigma_w$	Gust intensities (rms values of the linear gust velocities along the body stability axes)
$\sigma_{u_b}, \sigma_{v_b}, \sigma_{w_b}$	Gust intensities along the stability axes for an aircraft in banked flight
$\tau$	Pilot time delay
$\phi_u, \phi_v, \phi_w, \phi_p$	Power spectral density functions for the four statistically independent spatial gust random variables
$\phi_{nn}$	Power spectral density function for pilot remnant
$\psi_{w_0}$	Angle from which the wind blows measured in the horizontal plane from true north

# Contrails

	Spatial frequency
$\omega$	(1) Temporal frequency, or (2) random variable over the domain $\Omega_2$
$\omega_R$	Break frequency of pilot remnant transfer function
$\omega_s$	Pilot's circular scanning frequency
( ) <sub>a</sub>	Aileron
( ) <sub>b</sub>	Body stability axes
( ) <sub>c</sub>	Stochastic command input
( ) <sub>d</sub>	Dutch roll mode
( ) <sub>e</sub>	(1) Horizontal earth reference axes, or (2) elevator
( ) <sub>gs</sub>	Glide slope axes
( ) <sub>L</sub>	Longitudinal mode
( ) <sub>LD</sub>	Lateral-directional mode
( ) <sub>m</sub>	Rate-model
( ) <sub>n</sub> , ( ) <sub>n-1</sub>	nth and (n-1)st iterations
[ ] <sub>OL</sub>	Open loop
( ) <sub>p</sub>	(1) pilot variable, or (2) phugoid mode
( ) <sub>r</sub>	Real root equivalent parameter
( ) <sub>s</sub>	SAS variable
( ) <sub>sp</sub>	Short period mode
( ) <sub>T</sub>	Throttle
( )*	Scaled equivalent power spectrum or spectral factor
( ) <sup>.</sup>	Time derivative

# Contrails

$()^{-1}$	(1) Matrix inverse, or (2) inverse trigonometric function
$()'$	(1) Matrix (vector) transpose, or (2) primed stability derivative
$\nabla()$	Gradient

## INTRODUCTION

As the growth of air traffic spiralled upward in recent years, it became necessary to provide systems and procedures by which the safety and regularity of air terminal operations could be maintained under all weather conditions. The alternative was to allow weather at one airport to back up traffic throughout the country. The ultimate goal of this development was to achieve takeoffs and landings in zero visibility (Category III) conditions. To avoid multiple go-arounds and diversions to alternate airports in bad weather is both a cost effective and environmentally sound objective. For even though traffic growth may fluctuate with the prevailing economic conditions, the dual problems of minimizing fuel consumption and maintaining regularity will continue.

Recent improvements in technology have made it feasible to make more efficient use of our air terminal facilities. The Federal Aviation Administration in cooperation with other organizations, including the U.S. Air Force, is developing a new microwave landing system (MLS) which will provide landing guidance over a sector of air space spread out 60 degrees in azimuth to each side of runway centerline, upwards to 20 degrees in elevation, and out to at least 20 miles in range.

# *Contrails*

This broad sector will provide the flexibility to have several aircraft performing precision approaches simultaneously along different paths within the sector. In general, these paths will consist of both straight and curved segments. Other developments such as area navigation and improved conventional instrument landing systems (ILS) have provided capabilities which can complement or partially substitute for MLS.

One class of aircraft which will come into increasing use at the principal airport facilities is the short takeoff and landing (STOL) aircraft which can make short hauls to feeder airports. These STOL's typically have lower approach speeds and are capable of short radius turns and steep descent paths. These features make them well suited to feed into the approach patterns from the sides or upper ranges of the MLS sector while conventional aircraft make more direct centerline approaches.

In order to make optimum use of the new navigation and landing guidance equipment, a number of problems must be solved. These problems can be separated initially into two main divisions: (1) the air traffic control problem to specify the individual flight paths, and (2) the aircraft navigational and control problem to follow the pre-specified paths. A number of studies have been made to analyze these problems, particularly by the students and staff of Purdue University, several of whom used a STOL aircraft for their studies. The problem of specifying optimum approach paths

# Contrails

for multiple aircraft was investigated by Schmidt.<sup>1</sup> These approach paths are constrained by safety criteria to certain minimum separation distances. MLS poses new lateral as well as along-track separation problems, and these new separation requirements were treated by Cunningham.<sup>2</sup>

Quite obviously, the separation criteria are influenced to a great extent by the precision with which individual aircraft can follow a selected flight path. It is technically appealing to design a completely automatic system in order to fly the curved trajectories. This was done by Farrington.<sup>3</sup> However, many general aviation aircraft and STOL operators who cannot afford the triple redundant Category III quality automatic systems will continue to rely on manual approaches, at least down to Category II visual conditions.

Several studies have been made of the problems associated with these manual approaches. One tool that is required for analysis of the manual tracking task is a mathematical model of the human pilot, and considerable work has been done on such models. An analytical-verbal quasi-linear describing function model was described by McRuer.<sup>4</sup> This model relies principally upon classical frequency analysis methods to calculate the pilot parameters. An alternate optimal control pilot model was conceived by Anderson<sup>5</sup> and has been extended by several studies.<sup>6, 7, 8</sup>

# Contrails

Presenting the optimum display to the pilot is a problem that was investigated by Seitz<sup>9</sup> using optimal control methods. An extension of this study to the curved MLS trajectories was made by Cunningham<sup>10</sup> as he designed a pilot augmented control system. In his study he cited that by using feedback through the pilot the designer is unable to fully compensate for the open loop system poles, which have a strong effect upon the aircraft response. STOL aircraft, in particular, operate at low airspeeds where they experience significant control problems such as cross coupling of lateral and directional modes of response. Pope<sup>11</sup> used decoupling design methods to improve the aircraft response by a stability augmentation system (SAS) ahead of the pilot. Such an augmentation system can conceivably minimize the attitude and acceleration excursion problems and allow the pilot to concentrate on the path tracking task.

A complete numerical analysis of the path following response of a manually piloted aircraft system throughout an approach and landing would require use of the full non-linear equation of motion, aerodynamic and thrust data to cover decelerating flight and gear and flap changes, a pilot model which is valid for the non-linear tracking task, and a complete model of the atmospheric winds, wind shears, turbulence, and ground effect. However, in order to obtain comparative results this total analysis problem is usually reduced to its component parts or at least approximated in some manner.

# Contrails

Each of the atmospheric disturbances has been found to produce significant effects on aircraft tracking performance. Cherry<sup>12</sup> studied the response to a steady mean wind and turbulence and developed a feed forward guidance scheme to reduce tracking error in turning flight. Recent studies using the Air Force Flight Dynamics Laboratory Engineering Flight Simulator have demonstrated that realistic non-linear wind shears can also produce large tracking errors during ILS approaches.<sup>13</sup>

A number of studies have been conducted to analyze the gust response of the basic aircraft<sup>14</sup> or the aircraft with automatic control systems.<sup>15, 16</sup> Another study included a pilot model but only considered a single stability augmentation system.<sup>17</sup> These studies did indicate that SAS parameters affect gust response.

In most cases SAS is designed to correct response problems in flight regimes other than landing approach. This is especially true of military aircraft where the primary goal of SAS design may be to provide good flying qualities over a wide flight envelope or to provide a stable platform for weapon delivery or photo-reconnaissance. Even the augmentation included in approach control systems is designed to conventional flying quality specifications and only considers gust response as a secondary consideration. In fact, there is a wide range of poles with acceptable flying qualities<sup>18</sup> over which the gust response may differ significantly.

# Contrails

## Problem Definition

The cited references have indicated that atmospheric turbulence is a significant disturbance to aircraft, especially for STOL aircraft which have low wing loadings and inherent control problems. These studies have also shown that SAS is beneficial in relieving these control problems and that the parameters influence gust response.

When these factors were considered it became apparent that the influence of SAS parameters upon gust response of a manually piloted aircraft should be evaluated systematically in order to provide guidance for optimum tradeoffs between conventional flying qualities and gust response. In order to provide data for these decisions the object of this study was to vary the system open loop poles parametrically over the region of acceptable flying qualities by use of stability augmentation feedback gains and to evaluate the manually piloted aircraft response as a function of these system poles.

This problem was separated into two tasks: (1) to design SAS which provided specified open loop poles, and then for each feedback set (2) to calculate the piloted system response to atmospheric turbulence at points on an MLS trajectory. During this study these two tasks were formulated into separate quadratic optimal control problems for stochastic systems: (1) to calculate the SAS gains for specified open loop poles using a rate-model-in-the-performance-index algorithm, and (2) to calculate the pilot model gains

and system response for the same poles using a quadratic optimal pilot model. The SAS design method suggested by Van Dierendonck<sup>19, 20</sup> was extended to accomplish the parametric pole variation in this study, and the computer algorithm developed by Heath<sup>21</sup> was used for the numerical calculations. A special quadratic optimal pilot model was developed which was similar to that of Reference 5 but which was simplified to allow rapid system response calculations. The SAS designs were accomplished for the wings level decoupled longitudinal and lateral-directional modes, and the piloted system response was then evaluated for both wings level and banked flight conditions.

## System Description

The diagram of the complete manually piloted aircraft system is shown in Figure 1.1. This diagram illustrates the interaction of each of the system components. The elements of this system are summarized here.

The aircraft chosen for the analysis was the Breguet 941 STOL. The data used for this aircraft was essentially the same as that used in References 3 and 10. The system equations of motion were linearized about two general trim points representative of an MLS approach path: (1) wings level flight with non-zero climb angle, and (2) horizontal banked flight. The specific data used for SAS design was for three flap setting/airspeed combinations for the wings level case. The state sensors for the stability augmentation and flight

Figure 1.1 Piloted Aircraft System Diagram

# Contrails

director systems were assumed to have no measurement noise, and a perfect MLS signal was adopted. The studies cited previously showed that these error sources were sufficiently small in comparison to turbulence to be neglected for the purpose of this analysis.

The pilot was represented in the system by a mathematical model, which consisted of a portion representing the pilot's linear compensatory tracking response and a pilot remnant which lumped together the time varying and non-linear characteristics of the pilot tracking performance. The remnant was introduced as a noise source at the control wheel where it was summed with the linear inputs.

The gust inputs were modeled as a filtered stochastic disturbance for the system by using the Dryden gust model presented in Reference 18. In order to minimize the variables in the problem, the stationary gust intensities corresponding to severe turbulence for a single height above ground level (100 feet) were used for all trim points.

The flight director equations were derived to provide vertical and lateral flight path error signals for both wings level and banked flight.

The stability augmentation for this study was provided by state feedback to all four controls—elevator, throttle, aileron, and rudder. The aircraft pitch and roll attitudes, linear and angular velocities and the servo actuator states were fed back with gains that were determined by the quadratic optimal pole placement algorithm.

## Thesis Organization

The reader who wishes to follow the detailed development of the equations and the assumptions employed in this study should begin by reading the appendices. Appendix A contains the derivation of the state-vector equations for each component of the total system, and it contains a discussion of the aerodynamic and thrust data and trim equations. Appendix B contains a review of the quadratic optimal incomplete feedback control problem for infinite time linear stochastic systems and a discussion of the unique features of the computer algorithm employed in this study. Appendix C contains a discussion of a convenient transfer function calculation routine for systems in state-vector form, which was used to evaluate the pilot model in this analysis. Appendix D includes listings of the main FORTRAN IV computer programs used to calculate the system equations for each trim point and to perform the SAS design.

In Chapter II of the main text the system equations are presented in the necessary formulation for the SAS design and the pilot gains and system response calculation. The equations for the rate model pole placement algorithm are also described there. The numerical results of the study are presented in Chapter III followed by the summary and conclusions in the final chapter.

## GAINS CALCULATION FOR STABILITY AUGMENTATION SYSTEM AND PILOT MODEL

Appendix B presents the problem formulation and some computer algorithm details for the infinite time, linear stochastic system, optimal incomplete feedback control problem as shown by Heath.<sup>21</sup> The formulation for a single event was all that was required in this study. The following sections present the specific equations for stability augmentation system design and pilot model gain selection for the Breguet 941 aircraft. Heath's computer algorithm was used for both tasks.

Using symbolic notation the simplified infinite time linear stochastic system optimal incomplete feedback control problem is to find the fixed gain control matrix  $H$  such that the control

$$u = -Hy \quad (\text{II-1})$$

minimizes the cost function

$$J = \frac{1}{2} \lim_{t \rightarrow \infty} E[z'Qz] \quad (\text{II-2})$$

where  $E[ ]$  is the mathematical expectation; the response vector is

$$z = Dx + Tu \quad (\text{II-3})$$

the equivalent stochastic system differential equation is

$$\dot{x} = Ax + Bu + G\eta \quad (\text{II-4})$$

where  $\eta$  is a white noise disturbance (the symbolic derivative of the Wiener process,  $\beta$ ); and the observation vector is

$$y = Cx \quad (\text{II-5})$$

Discussion of the response weighting matrix,  $Q$ , will be deferred until the section on program results.

### Problem Formulation for Stability Augmentation System Design

Several variations in stability augmentation system design were attempted. However, the basic design technique employed was the rate-model-in-the-performance-index method described by Van Dierendonck<sup>19, 20</sup> and used by Heath<sup>21</sup> in his sample problem. In this method the response vector of Equation (II-3) is obtained by subtracting the system differential equation for a model with desired dynamics from the basic System Differential Equation (II-4). If the model equation is as follows, without actuators or controls,

$$\dot{x}_m = A_m x_m + G_m \eta \quad (\text{II-6})$$

then the response vector is

$$z = \dot{x} - \dot{x}_m = Ax - A_m x_m + Bu + (G - G_m) \eta \quad (\text{II-7})$$

Or, assuming for small errors,  $x = x_m$ , and taking the same disturbance model ( $G = G_m$ ), then

$$z = (A - A_m)x + Bu \quad (\text{II-8})$$

The D and T matrices are then formed by eliminating the rows which contained all zeros in both the  $(A - A_m)$  and B matrices.

The trim points chosen for stability augmentation design were taken to be wings level flight. Consequently, the longitudinal and lateral-directional modes of response decoupled and could be considered separately. The definitions of the elements of the system equations for these two response modes and the development of the model equations are presented in the following sections. The basic system equations were taken from Appendix A after simplification to level flight.

### Longitudinal Mode SAS Design Equations

For the longitudinal mode the state vector elements were

$$x' = [\underline{u}, \alpha, q, \theta, \delta_e, \delta_T, \delta_{e_c}, \delta_{T_c}] \quad (\text{II-9})$$

where  $\delta_{e_c}$  and  $\delta_{T_c}$  were states for the first order filters of the stochastic disturbance process.

The observation elements for full state feedback were

$$y' = [\underline{u}, \alpha, q, \theta, \delta_e, \delta_T, \delta_{e_c}, \delta_{T_c}] \quad (\text{II-10})$$

# Contrails

The control vector was

$$u' = [\delta_{e_s}, \delta_{T_s}] \quad (\text{II-11})$$

The disturbance vector was

$$n' = [\eta_e, \eta_T] \quad (\text{II-12})$$

and the response vector was

$$z' = [\Delta \dot{u}, \Delta \dot{\alpha}, \Delta \dot{q}, \dot{\delta}_e, \dot{\delta}_T] \quad (\text{II-13})$$

The columns of the A-matrix were as follows, where the subscripts denote the state variable of which each element in a given column was a coefficient. ( $O_{n \times m}$  signifies an n by m order zero matrix.)

$$A_{\underline{u}} = \begin{bmatrix} f_1 C_{x_u} \\ f_3 f_1 C_{z_u} \\ f_y (C_{m_u} + f_3 f_8 C_{m_\alpha} f_1 C_{z_u}) \\ O_5 \end{bmatrix}$$

# Contrails

$$A_{\alpha} = \begin{bmatrix} f_1 C_{x_{\alpha}} \\ f_1 f_3 C_{z_{\alpha}} \\ f_Y (C_{m_{\alpha}} + f_2 f_3 C_{m_{\alpha}} C_{z_{\alpha}}) \\ 0_5 \end{bmatrix}$$

$$A_q = \begin{bmatrix} 0 \\ f_3 (1 + f_2 C_{z_q}) \\ f_4 [C_{m_q} + f_3 C_{m_{\alpha}} (1 + f_2 C_{z_q})] \\ 1 \\ 0_4 \end{bmatrix}$$

$$A_{\theta} = \begin{bmatrix} -g \cos \theta_o / U \\ -f_3 g \sin \theta_o / U \\ -f_3 f_4 C_{m_{\alpha}} g \sin \theta_o / U \\ 0_5 \end{bmatrix}$$

# Contrails

$$A_{\delta_e} = \begin{bmatrix} 0 \\ f_1 f_3 c C_{m_{\delta_e}} / l_t \\ f_Y C_{m_{\delta_e}} (1 + f_2 f_3 c C_{m_{\dot{\alpha}}} / l_t) \\ 0 \\ -\omega_e \\ 0_3 \end{bmatrix}$$

$$A_{\delta_T} = \begin{bmatrix} f_1 C_{x_{\delta_T}} \\ f_1 f_3 C_{z_{\delta_T}} \\ f_Y (C_{m_{\delta_T}} + f_2 f_3 C_{z_{\delta_T}} C_{m_{\dot{\alpha}}}) \\ 0_2 \\ -\omega_T \\ 0_2 \end{bmatrix}$$

$$A_{\delta_{ec}} = \begin{bmatrix} 0_6 \\ -\omega_{ce} \\ 0 \end{bmatrix}$$

$$A_{\delta_{Tc}} = \begin{bmatrix} 0_7 \\ -\omega_{cT} \end{bmatrix}$$

(II-14)

# Contrails

where  $\omega_{c_e}$  and  $\omega_{c_T}$  are the break frequencies for the first order stochastic disturbance process. The parameters in the matrix elements are defined in Appendix A.

The B-matrix was as follows

$$B = \begin{bmatrix} O_{4 \times 2} \\ - - - - \\ \omega_e & 0 \\ 0 & \omega_T \\ - - - - \\ O_{2 \times 2} \end{bmatrix} \quad (\text{II-15})$$

The C-matrix was an eighth order identity matrix; and the G-matrix was as follows

$$G = \begin{bmatrix} O_{6 \times 2} \\ - - - - \\ K_e & 0 \\ 0 & K_T \end{bmatrix} \quad (\text{II-16})$$

where in order to provide a unit co-variance for each disturbance process

$$K_e = \sqrt{2\omega_{c_e}} \quad K_T = \sqrt{2\omega_{c_T}} \quad (\text{II-17})$$

These equations allowed full state feedback SAS design. Incomplete feedback design was accomplished by redefining the observation vector, Equation (II-10), and observation

C-matrix to eliminate the appropriate states. Washout filters, which are required in actual augmentation system implementation, could also be included by introduction of elements into the state vector, Equation (II-9), and by proper definition of the observations.

### Longitudinal Mode Rate Model Equations

The model state coefficient  $A_m$ -matrix was formed by equating most of the elements of  $A_m$  to the equivalent elements in  $A$ . However, the model had no actuators or controls. Instead, the actuator state coefficients of  $A$  became coefficients of the stochastic command input states in the model. Also, in order to vary the dynamics of the model, four terms in the  $A_m$ -matrix were chosen for recalculation. These elements were the ones which contained the stability derivatives ( $C_{m_q}$ ,  $C_{m_\alpha}$ ,  $C_{x_u}$ ,  $C_{z_u}$ ) most affecting the short period and phugoid frequencies and dampings as shown by Blakelock.<sup>22</sup> The terms were  $a_{11}$ ,  $a_{21}$ ,  $a_{32}$ , and  $a_{33}$ . The

D-matrix then became

$$D = \begin{bmatrix} (a_{11}-a_{m11}) & 0 & 0 & 0 & a_{15} & a_{16} & -a_{15} & -a_{16} \\ (a_{21}-a_{m21}) & 0 & 0 & 0 & a_{25} & a_{26} & -a_{25} & -a_{26} \\ 0 & (a_{32}-a_{m32}) & (a_{33}-a_{m33}) & 0 & a_{35} & a_{36} & -a_{35} & -a_{36} \\ 0 & 0 & 0 & 0 & -\omega_e & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -\omega_T & 0 & 0 \end{bmatrix}$$

(II-18)

# Contrails

and the T-matrix became

$$T = \begin{bmatrix} O_{3 \times 2} \\ - & - & - \\ \omega_e & 0 \\ 0 & \omega_T \end{bmatrix} \quad (\text{II-19})$$

The longitudinal mode pole locations were defined by the upper left (4 x 4) partition of the A-matrix. With zero and unit elements inserted as appropriate this matrix became

$$A_L = \begin{bmatrix} a_{11} & a_{12} & 0 & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ 0 & 0 & 1 & 0 \end{bmatrix} \quad (\text{II-20})$$

The characteristic equation for this system was then

$$\det(sI - A_L) = \det \begin{bmatrix} (s - a_{11}) & -a_{12} & 0 & -a_{14} \\ -a_{21} & (s - a_{22}) & -a_{23} & -a_{24} \\ -a_{31} & -a_{32} & (s - a_{33}) & -a_{34} \\ 0 & 0 & -1 & s \end{bmatrix} = 0 \quad (\text{II-21})$$

# Contrails

Expanding this determinant

$$\begin{aligned}
 \det(sI-A_L) = & s^4 - (a_{11}+a_{22}+a_{33})s^3 + (a_{11}a_{22}+a_{11}a_{33}+ \\
 & +a_{22}a_{33}-a_{12}a_{21}-a_{23}a_{32}-a_{34})s^2 + \\
 & (a_{11}a_{23}a_{32}-a_{14}a_{31}-a_{24}a_{32}-a_{12}a_{31}a_{23}+ \\
 & a_{12}a_{21}a_{33}-a_{11}a_{22}a_{33}+a_{11}a_{34}+a_{22}a_{34})s + \\
 & (a_{14}a_{22}a_{31}-a_{14}a_{21}a_{32}+a_{24}a_{32}a_{11}- \\
 & a_{12}a_{31}a_{24}-a_{12}a_{21}a_{34}-a_{11}a_{22}a_{34}) = 0
 \end{aligned}$$

(II-22)

At the same time, for phugoid frequency and damping,  $\omega_p$  and  $\zeta_p$ , and for short period frequency and damping,  $\omega_{sp}$  and  $\zeta_{sp}$ , an alternate expression for the characteristic equation was

$$\begin{aligned}
 \det(sI-A_L) = & (s^2+2\zeta_p\omega_p s+\omega_p^2)(s^2+2\zeta_{sp}\omega_{sp} s+\omega_{sp}^2) \\
 = & s^4+(2\zeta_p\omega_p+2\zeta_{sp}\omega_{sp})s^3+(\omega_p^2+4\zeta_p\omega_p\zeta_{sp}\omega_{sp}+ \\
 & \omega_{sp}^2)s^2+(2\zeta_p\omega_p\omega_{sp}^2+2\zeta_{sp}\omega_{sp}\omega_p^2)s+\omega_p^2\omega_{sp}^2 \\
 = & 0
 \end{aligned}$$

(II-23)

For the two expressions to be identical, coefficients of like powers of  $s$  had to be equal. We then defined functions  $f_i(x)$ ,  $i=1$  to  $4$ , as the difference between coefficients for each power of  $s$ .

# Contrails

$$f_1(x) = a_{11} + a_{22} + a_{33} + 2\zeta_p \omega_p + 2\zeta_{sp} \omega_{sp} = 0$$

$$f_2(x) = a_{11}a_{22} + a_{11}a_{33} + a_{22}a_{33} - a_{12}a_{21} - a_{23}a_{32} - a_{34} - (\omega_p^2 + 4\zeta_p \omega_p \zeta_{sp} \omega_{sp} + \omega_{sp}^2) = 0$$

$$f_3(x) = a_{11}a_{23}a_{32} - a_{14}a_{31} - a_{24}a_{32} - a_{12}a_{31}a_{23} + a_{12}a_{21}a_{33} - a_{11}a_{22}a_{33} + a_{11}a_{34} + a_{22}a_{34} - (2\zeta_p \omega_p \omega_{sp}^2 + 2\zeta_{sp} \omega_{sp} \omega_p^2) = 0$$

$$f_4(x) = a_{14}a_{22}a_{31} - a_{14}a_{21}a_{32} + a_{24}a_{32}a_{11} - a_{12}a_{31}a_{24} - a_{12}a_{21}a_{34} - a_{11}a_{22}a_{34} - \omega_p^2 \omega_{sp}^2 = 0 \quad (\text{II-24})$$

where  $x' = [x_1, x_2, x_3, x_4] = [a_{11}, a_{21}, a_{32}, a_{33}]$  and the functions  $f_i(x)$  composed a vector  $F'(x) = [f_1(x), f_2(x), f_3(x), f_4(x)]$ .

To place the poles arbitrarily, values for  $\omega_p$ ,  $\zeta_p$ ,  $\omega_{sp}$ , and  $\zeta_{sp}$  were selected. Then Equations (II-24) were solved for  $x$ . The solutions yielded  $x_0$  such that  $F_0 = F(x_0) = [0]$ . This solution was obtained by use of the Newton-Raphson iteration which employed the equation

$$x_n = x_{n-1} - \left| \frac{\partial F(x_{n-1})}{\partial x} \right|^{-1} F(x_{n-1}) \quad (\text{II-25})$$

where  $x_1$  was a suitable estimate for  $x_0$  and  $x_n = x_0$  when  $(F'F)^{1/2} < \epsilon$ .

# Contrails

The partial derivatives required in Equation (II-25) were obtained as follows:

$$\frac{\partial f_1}{\partial x_1} = 1, \quad \frac{\partial f_1}{\partial x_2} = 0, \quad \frac{\partial f_1}{\partial x_3} = 0, \quad \frac{\partial f_1}{\partial x_4} = 1$$

$$\frac{\partial f_2}{\partial x_1} = a_{22} + a_{33}, \quad \frac{\partial f_2}{\partial x_2} = -a_{12}, \quad \frac{\partial f_2}{\partial x_3} = -a_{23}, \quad \frac{\partial f_2}{\partial x_4} = a_{11} + a_{22}$$

$$\frac{\partial f_3}{\partial x_1} = a_{23}a_{32} - a_{22}a_{33} + a_{34}, \quad \frac{\partial f_3}{\partial x_2} = a_{12}a_{33}$$

$$\frac{\partial f_3}{\partial x_3} = a_{11}a_{23} - a_{24}, \quad \frac{\partial f_3}{\partial x_4} = a_{12}a_{21} - a_{11}a_{22}$$

$$\frac{\partial f_4}{\partial x_1} = a_{24}a_{32} - a_{22}a_{34}, \quad \frac{\partial f_4}{\partial x_2} = -a_{14}a_{32} - a_{12}a_{34}$$

$$\frac{\partial f_4}{\partial x_3} = -a_{14}a_{21} + a_{11}a_{24}, \quad \frac{\partial f_4}{\partial x_4} = 0 \quad (\text{II-26})$$

## Lateral-Directional Mode SAS Design Equations

For the lateral-directional mode the state vector elements were

$$x' = [p, r, \beta, \phi, \delta_a, \delta_r, \delta_{a_c}, \delta_{r_c}] \quad (\text{II-27})$$

The full state feedback observation vector was

$$y' = [p, r, \beta, \phi, \delta_a, \delta_r, \delta_{a_c}, \delta_{r_c}] \quad (\text{II-28})$$

# Contrails

where  $\delta_{a_c}$  and  $\delta_{r_c}$  were disturbance input states. The control vector was

$$u' = [\delta_{a_s}, \delta_{r_s}] \quad (\text{II-29})$$

The disturbance vector was

$$\eta' = [\eta_a, \eta_r] \quad (\text{II-30})$$

and the response vector was

$$z' = [\Delta \dot{p}, \Delta \dot{r}, \Delta \dot{\beta}, \dot{\delta}_a, \dot{\delta}_r] \quad (\text{II-31})$$

The columns of the A-matrix were

$$A_p = \begin{bmatrix} f_6 C_{1p}' \\ f_7 C_{np}' \\ 0 \\ 1 \\ 0_4 \end{bmatrix}, \quad A_r = \begin{bmatrix} f_6 C_{1r}' \\ f_7 C_{nr}' \\ -1 \\ \tan \theta_0 \\ 0_4 \end{bmatrix}, \quad A_\beta = \begin{bmatrix} f_x C_{1\beta}' \\ f_z C_{n\beta}' \\ f_1 C_{y\beta}' \\ 0_5 \end{bmatrix}$$

$$A_{\phi} = \begin{bmatrix} 0 \\ 0 \\ g \cos \theta_0 / U \\ 0_5 \end{bmatrix}, \quad A_{\delta_a} = \begin{bmatrix} f_x C_{l\delta_a}' \\ f_z C_{n\delta_a}' \\ f_1 C_{y\delta_a}' \\ 0 \\ -\omega_a \\ 0_3 \end{bmatrix}, \quad A_{\delta_r} = \begin{bmatrix} f_x C_{l\delta_r}' \\ f_z C_{n\delta_r}' \\ f_1 C_{y\delta_r}' \\ 0_2 \\ -\omega_r \\ 0_2 \end{bmatrix}$$

$$A_{\delta_{ac}} = \begin{bmatrix} 0_6 \\ -\omega_{ca} \\ 0 \end{bmatrix}, \quad A_{\delta_{rc}} = \begin{bmatrix} 0_7 \\ -\omega_{cr} \end{bmatrix} \tag{II-32}$$

where  $\omega_{ca}$  and  $\omega_{cr}$  are the break frequencies of the stochastic disturbance process.

The B-matrix was

$$B = \begin{bmatrix} 0_{6 \times 2} \\ \omega_a & 0 \\ 0 & \omega_r \end{bmatrix} \tag{II-33}$$

The observation C-matrix was an eighth order identity matrix; and the G-matrix was

$$G = \begin{bmatrix} 0_{6 \times 2} & - & - & - & - & - \\ \sqrt{2\omega} c_a & & & & & 0 \\ 0 & & & & \sqrt{2\omega} c_r & \end{bmatrix} \quad (\text{II-34})$$

### Lateral-Directional Mode Rate Model Equations

The lateral-directional model  $A_m$ -matrix was formed in a manner similar to the longitudinal model. However, the four coefficients chosen for recalculation were the elements  $a_{11}$ ,  $a_{13}$ ,  $a_{22}$ , and  $a_{23}$ . The stability derivatives in these elements ( $C_{l_p}$ ,  $C_{l_\beta}$ ,  $C_{n_r}$ ,  $C_{n_\beta}$ ) caused the most change in the lateral-directional mode frequency and damping and real roots.

The D-matrix then became

$$D = \begin{bmatrix} (a_{11} - a_{m11}) & 0 & (a_{13} - a_{m13}) & 0 & a_{15} & a_{16} & -a_{15} & -a_{16} \\ 0 & (a_{22} - a_{m22}) & (a_{23} - a_{m23}) & 0 & a_{25} & a_{26} & -a_{25} & -a_{26} \\ 0 & 0 & 0 & 0 & a_{35} & a_{36} & -a_{35} & -a_{36} \\ 0 & 0 & 0 & 0 & -\omega_a & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -\omega_r & 0 \end{bmatrix} \quad (\text{II-35})$$

and the T-matrix became

$$T = \begin{bmatrix} 0_{3 \times 2} \\ \omega_a & 0 \\ 0 & \omega_r \end{bmatrix} \quad (\text{II-36})$$

Again, the upper left (4 x 4) partition of the A-matrix defined the pole locations for the lateral-directional mode. With zeros and ones inserted appropriately, this matrix became

$$A_{LD} = \begin{bmatrix} a_{11} & a_{12} & a_{13} & 0 \\ a_{21} & a_{22} & a_{23} & 0 \\ 0 & 1 & a_{33} & a_{34} \\ 1 & a_{42} & 0 & 0 \end{bmatrix} \quad (\text{II-37})$$

For the lateral-directional mode the poles generally conform to an oscillatory dutch-roll mode specified by frequency and damping,  $\omega_d$  and  $\zeta_d$ , and two real poles, the roll convergence pole, with time constant  $T_R$ , and the spiral divergence pole, with time constant  $T_S$ . The spiral mode is generally unstable or near neutral stability. Van Dierendonck<sup>19</sup> removed the unstable spiral pole by a suitable matrix transformation. However, the spiral mode for the

# Contrails

Breguet 941 was found to be stable, and was retained in the analysis.

The characteristic equation for the lateral-directional matrix of Equation (II-37) has the two alternate expressions

$$\det(sI - A_{LD}) = (s^2 + 2\zeta_d \omega_d s + \omega_d^2) (s + 1/T_R) (s + 1/T_S) = 0 \quad (\text{II-38})$$

We defined a pseudo frequency and damping for the real poles,  $\omega_r$  and  $\zeta_r$ , such that

$$(s + 1/T_R) (s + 1/T_S) = (s^2 + 2\zeta_r \omega_r s + \omega_r^2) \quad (\text{II-39})$$

where

$$\omega_r^2 = 1/(T_R T_S), \quad \zeta_r = (1/T_R + 1/T_S)/(2\omega_r) \quad (\text{II-40})$$

Having made these substitutions, we expanded both sides of Equation (II-38) and subtracted coefficients of like powers of  $s$  to define the vector function  $F'(x) = [f_1, f_2, f_3, f_4]$  for the lateral-directional mode, where

$$\begin{aligned} f_1(x) &= a_{11} + a_{22} + a_{33} + 2\zeta_d \omega_d + 2\zeta_r \omega_r = 0 \\ f_2(x) &= a_{23} + a_{11} a_{33} + a_{11} a_{22} - a_{12} a_{21} + a_{22} a_{33} - \\ &\quad (\omega_d^2 \omega_r^2 + 2\zeta_d \omega_d + 2\zeta_r \omega_r) = 0 \end{aligned}$$

# Contrails

$$\begin{aligned}
 f_3(x) &= -a_{11}a_{23} + a_{31}a_{21} - a_{23}a_{34}a_{42} - a_{11}a_{22}a_{33} - \\
 &\quad a_{34}a_{13} + a_{12}a_{21}a_{33} - (2\zeta_d\omega_d\omega_r^2 + 2\zeta_r\omega_r\omega_d^2) = 0 \\
 f_4(x) &= -a_{12}a_{34}a_{23} + a_{22}a_{34}a_{13} + a_{11}a_{23}a_{34}a_{42} - \\
 &\quad a_{13}a_{21}a_{34}a_{42} - \omega_d^2\omega_r^2 = 0 \tag{II-41}
 \end{aligned}$$

Differentiating, we then obtained the partial derivatives required in Equation (II-25)

$$\begin{aligned}
 \frac{\partial f_1}{\partial x_1} &= 1, & \frac{\partial f_1}{\partial x_2} &= 0, & \frac{\partial f_1}{\partial x_3} &= 1, & \frac{\partial f_1}{\partial x_4} &= 0 \\
 \frac{\partial f_2}{\partial x_1} &= a_{33} + a_{22}, & \frac{\partial f_2}{\partial x_2} &= 0, & \frac{\partial f_2}{\partial x_3} &= a_{11} + a_{33}, & \frac{\partial f_2}{\partial x_4} &= 1 \\
 \frac{\partial f_3}{\partial x_1} &= -a_{23} - a_{22}a_{33}, & \frac{\partial f_3}{\partial x_2} &= a_{21} - a_{34}, & \frac{\partial f_3}{\partial x_3} &= -a_{11}a_{33} \\
 & & \frac{\partial f_3}{\partial x_4} &= -a_{11} - a_{34}a_{42} \\
 \frac{\partial f_4}{\partial x_1} &= a_{23}a_{34}a_{42}, & \frac{\partial f_4}{\partial x_2} &= a_{22}a_{34} - a_{21}a_{34}a_{42} \\
 & & \frac{\partial f_4}{\partial x_3} &= a_{34}a_{13}, & \frac{\partial f_4}{\partial x_4} &= -a_{12}a_{34} + a_{11}a_{34}a_{42}
 \end{aligned} \tag{II-42}$$

## Problem Formulation for Pilot Gains and System Response Calculation

The pilot gains and system response were calculated for both the complete piloted system in banked flight trim conditions and the decoupled piloted system for the level flight

trim conditions. The equations for the full system are presented here. They can readily be reduced to the decoupled subcases by zeroing the bank angle and separating the longitudinal and lateral-directional mode states and matrix coefficients.

The total system includes the basic aircraft and control surface dynamics, the servo-actuators, the stability augmentation system, the gust disturbance model, the positional error model, the flight director system, and the pilot model which includes the pilot/system control inputs, pilot states, remnant model, observation equations, and performance functional. In the following sections the full system matrix differential equation is generated beginning with the basic aircraft and adding the equations for each of the other system components. The equations are combined in a manner such that a special set of control inputs is defined to become the system control vector with associated system observation matrix and response vector. The control matrix then contains the pilot model gains which are to be computed by the Heath computer algorithm.<sup>21</sup> The computer algorithm calculates the state and response co-variance matrices during the gain computation; thus, the gains and system response are obtained simultaneously.

The total system is developed in a building-block form by defining the state, control, observation, and disturbance vectors and coefficient matrices for each component, then

retaining each sub-matrix as a partition of the total system. As an aid to proper location of each matrix partition in relation to the appropriate system states the order of each zero matrix is indicated by a subscript:  $O_{n \times m}$  being an  $n$  by  $m$  zero matrix. Also,  $I_n$  is an  $n$ th order identity matrix.

## Aircraft, Servo, SAS, Gust Model System

The system which formed the basis for the total piloted system is the basic airframe-servo-actuator-SAS system with a given set of SAS gains computed as previously described. The simple stochastic actuator disturbance model was removed and replaced by the stochastic gust model, which is the random disturbance for the piloted system. Since the SAS gains were to be varied parametrically during this study, they were isolated into a separate SAS feedback equation. The state vector for this basic system is

$$\begin{aligned} x_1' = [ & \underline{u}, \alpha, q, \theta, p, r, \beta, \phi, \delta_e, \delta_a, \delta_r, \delta_T, \underline{u}_g, \\ & \beta_g, \beta_g', \alpha_g, \alpha_g', p_g ] \end{aligned} \quad (\text{II-43})$$

The basic aircraft control vector is

$$u_1' = [\delta_{e_c}, \delta_{a_c}, \delta_{r_c}, \delta_{T_c}] \quad (\text{II-44})$$

The stochastic disturbance vector is

$$n_1' = [n_u, n_\beta, n_\alpha, n_p] \quad (\text{II-45})$$

# Contrails

and the pilot control inputs, which add to the SAS feedback, are given by the vector

$$v_1' = [\delta_{e_p}, \delta_{a_p}] \quad (\text{II-46})$$

where the pilot was assumed to control only by elevator and aileron motion.

The basic system equation is

$$\dot{x}_1 = A_1 x_1 + B_1 u_1 + G_1 \eta_1 \quad (\text{II-47})$$

and the SAS feedback equation is

$$u_1 = F_1 x_1 + G_2 v_1 \quad (\text{II-48})$$

The matrix coefficients are taken from the equations of Appendix A. The  $A_1$ -matrix terms come from Equations (A-29), (A-57 to 60), and (A-65 to 68). The columns of the  $A_1$ -matrix are

$$A_{1u} = \begin{bmatrix} f_1 C_{x_u} \\ f_3 (f_1 C_{z_u} + Q_0) \\ f_y [C_{m_u} + f_3 f_8 C_{m_\alpha} (Q_0 + f_1 C_{z_u})] \\ 0_3 \\ -R_0 \\ 0_{11} \end{bmatrix}$$

# Contrails

$$A_{1\alpha} = \begin{bmatrix} f_1 C_{x_\alpha} - Q_0 \\ f_1 f_3 C_{z_\alpha} \\ f_y (C_{m_\alpha} + f_2 f_3 C_{m_\alpha} C_{z_\alpha}) \\ 0_{15} \end{bmatrix}$$

$$A_{1q} = \begin{bmatrix} 0 \\ f_3 (1 + f_2 C_{z_q}) \\ f_4 [C_{m_q} + f_3 C_{m_\alpha} (1 + f_2 C_{z_q})] \\ \cos \phi_0 \\ -f_{12} R_0 \\ -f_{13} R_0 \\ 0_{12} \end{bmatrix}$$

$$A_{1\theta} = \begin{bmatrix} -g \cos \theta_0 / U \\ -f_3 g \sin \theta_0 / U \\ -f_4 f_3 C_{m_\alpha} g \sin \theta_0 / U \\ 0_4 \\ \dot{\psi}_0 \\ 0_{10} \end{bmatrix}$$

$$A_{1\alpha_g} = \begin{bmatrix} -f_1 C_{x_\alpha} \\ -[f_1 f_3 C_{z_\alpha} + f_2 f_3 (C_{z_q} - C_{z_\alpha^*}) U/L_w] \\ -\{f_y (C_{m_\alpha} + f_2 f_3 C_{m_\alpha^*} C_{z_\alpha}) + f_y f_8 [C_{m_q} - C_{m_\alpha^*} + \\ f_2 f_3 C_{m_\alpha^*} (C_{z_q} - C_{z_\alpha^*})] U/L_w\} \\ 0_{12} \\ -U/L_w \\ 0_2 \end{bmatrix}$$

# Contrails

$$A_{1_{\alpha'g}} = \begin{bmatrix} 0 \\ f_2 f_3 (C_{z_q} - C_{z_{\alpha'}}) (1 - \sqrt{3}) (\sigma_w / L_w) \sqrt{U / L_w} \\ f_y f_8 [C_{m_q} - C_{m_{\alpha'}} + f_2 f_3 C_{m_{\alpha'}} (C_{z_q} - C_{z_{\alpha'}})] (1 - \sqrt{3}) (\sigma_w / L_w) \sqrt{U / L_w} \\ 0_{12} \\ (1 - \sqrt{3}) (\sigma_w / L_w) \sqrt{U / L_w} \\ -U / L_w \\ 0 \end{bmatrix}$$

$$A_{1_{p_g}} = \begin{bmatrix} 0_4 \\ -f_6 C_{1_p}' \\ -f_7 C_{n_p}' \\ 0_{11} \\ -\pi U / (4b) \end{bmatrix} \quad (\text{II-49})$$

where each subscript on  $A_1$  is the state for which each column element is a coefficient.

From Equations (A-34) the  $B_1$ -matrix is

$$B_1 = \begin{bmatrix} 0_{8 \times 4} & - & - \\ 10I_3 & 0_3 & \\ 0_{1 \times 3} & 1 & \\ - & - & - \\ 0_{6 \times 4} & & \end{bmatrix} \quad (\text{II-50})$$

# Contrails

From Equations (A-57 to 60) and (A-65 to 68) the  $G_1$ -matrix columns are

$$G_{1n_u} = \begin{bmatrix} O_{12} \\ (\sigma_u/U) \sqrt{2U/L_u} \\ O_5 \end{bmatrix} \quad G_{1n_\beta} = \begin{bmatrix} O_4 \\ -C_{l_{r_g}} (\sigma_v/U) \sqrt{3U/L_v} \\ -C_{n_{r_g}} (\sigma_v/U) \sqrt{3U/L_v} \\ O_7 \\ (\sigma_v/U) \sqrt{3U/L_v} \\ 1 \\ O_3 \end{bmatrix}$$

$$G_{1n_\alpha} = \begin{bmatrix} 0 \\ f_2 f_3 (C_{z_q} - C_{z_\alpha^*}) (\sigma_w/U) \sqrt{3U/L_w} \\ f_y f_8 [C_{m_q} - C_{m_\alpha^*} + f_2 f_3 C_{m_\alpha^*} (C_{z_q} - C_{z_\alpha^*})] (\sigma_w/U) \sqrt{3U/L_w} \\ O_{12} \\ (\sigma_w/U) \sqrt{3U/L_w} \\ 1 \\ 0 \end{bmatrix}$$

$$G_{1n_p} = \begin{bmatrix} O_{17} \\ \pi \sigma_w / (4b) \sqrt{(\pi U / L_w) (.8) [\pi L_w / (4b)]^{1/3}} \end{bmatrix} \quad (II-51)$$

# Contrails

The feedback matrix comes from the optimal SAS gain calculation. Since the closed-loop state coefficient matrix is given by either  $(A_1+B_1F_1)$  or  $(A-BHC)$  of Equations (II-1, 4, 5) then

$$F_1 = -HC \quad (II-52)$$

The  $G_2$ -matrix defines the pilot control inputs (elevator and aileron)

$$G_2 = \begin{bmatrix} I_2 & - & - \\ 0_{2 \times 2} & & \end{bmatrix} \quad (II-53)$$

With SAS feedback the system equation becomes

$$\dot{x}_1 = (A_1+B_1F_1)x + B_1G_2v_1 + G_1n_1 \quad (II-54)$$

## Position Error Model

The displacement or position error model equations are now added to the system. If we define the position state vector

$$x_2' = [\psi, d_y, d_z] \quad (II-55)$$

the displacement equations can then be written as

$$\dot{x}_2 = A_2x_2 + A_3x_1 \quad (II-56)$$

where the matrix coefficients come from Equations (A-29, 41).

The  $A_2$ -matrix is

$$A_2 = \begin{bmatrix} 0 & | & \\ U \cos \theta_o \cos \phi_o & | & 0_{3 \times 2} \\ U \sin \phi_o & | & \end{bmatrix} \quad (\text{II-57})$$

and the  $A_3$ -matrix is

$$A_3 = \begin{bmatrix} 0 & 0 & \sin \phi_o & 0 & 0 & \cos \phi_o / \cos \theta_o & 0' \\ 0 & 0 & 0 & -U \sin \phi_o & 0 & 0 & U' \\ 0 & -U & 0 & U \cos \phi_o & 0 & 0 & 0' \end{bmatrix} \quad 0_{3 \times 11} \quad (\text{II-58})$$

The displacement equations are then added to the system by defining the new state vector

$$x_3' = [x_2', x_1'] \quad (\text{II-59})$$

The combined equation is

$$\dot{x}_3 = \begin{bmatrix} A_2 & | & A_3 \\ \hline 0_{18 \times 3} & | & A_1 + B_1 F_1 \end{bmatrix} x_3 + \begin{bmatrix} 0_{3 \times 2} \\ B_1 G_2 \end{bmatrix} v_1 + \begin{bmatrix} 0_{3 \times 4} \\ G_1 \end{bmatrix} \eta_1 \quad (\text{II-60})$$

### Pilot Model

The final component equations to be added to the complete system are the pilot model equations. The gain-lead-delay pilot model, Equations (A-76, 79), were used. We

# Contrails

define the pilot state vector

$$x_4' = [x_{p_L}, x_{p_{LD}}] \quad (\text{II-61})$$

and the system control vector

$$u' = [u_{p_L}, u_{p_{LD}}] \quad (\text{II-62})$$

One must note that this system control vector is not exactly equal to the pilot control inputs, but is related through Equation (A-79). The pilot model equations can then be written as

$$\dot{x}_4 = F_2 x_4 + B_2 u \quad (\text{II-63})$$

and

$$v_1 = H_1 x_4 + H_2 u \quad (\text{II-64})$$

where

$$F_2 = \begin{bmatrix} -2/\tau & 0 \\ 0 & -2/\tau \end{bmatrix} \quad B_2 = \begin{bmatrix} 4/\tau & 0 \\ 0 & 4/\tau \end{bmatrix}$$
$$H_1 = I_2 \quad H_2 = -I_2 \quad (\text{II-65})$$

The quasi-linear pilot model also includes a remnant model.

We define the remnant state vector

$$x_5' = [n_{\delta_e}, n_{\delta_a}] \quad (\text{II-66})$$

and the remnant stochastic disturbance vector

$$\eta_2' = [\eta_{n_e}, \eta_{n_a}] \quad (\text{II-67})$$

Then from Equation (A-78) the remnant model is

$$\dot{x}_5 = A_4 x_5 + G_3 \eta_2 \quad (\text{II-68})$$

where

$$A_4 = \begin{bmatrix} -\omega_{R_e} & 0 \\ 0 & -\omega_{R_a} \end{bmatrix} \quad G_3 = \begin{bmatrix} \sigma_{Y_L} \sqrt{\pi K_{R_e}} & 0 \\ 0 & \sigma_{Y_{LD}} \sqrt{\pi K_{R_a}} \end{bmatrix} \quad (\text{II-69})$$

and  $\sigma_{Y_L} = \sigma_{u_{P_L}}$ ,  $\sigma_{Y_{P_{LD}}} = \sigma_{u_{P_{LD}}}$  as discussed in Appendix A.

### Complete Piloted System

The pilot model is now added to complete the system.

We define the total state vector

$$\begin{aligned} x' &= [x_4', x_3', x_5'] \\ &= [x_{p_L}, x_{p_{LD}}, \psi, d_y, d_z, \underline{u}, \alpha, q, \theta, p, r, \beta, \phi, \\ &\quad \delta_e, \delta_a, \delta_r, \delta_T, \underline{u}_g, \beta_g, \beta_g', \alpha_g, \alpha_g', p_g, n_{\delta_e}, n_{\delta_a}] \end{aligned} \quad (\text{II-70})$$

We also define the total disturbance vector

# Contrails

$$\eta' = [\eta_1', \eta_2'] = [\eta_u, \eta_\beta, \eta_\alpha, \eta_p, \eta_{n_e}, \eta_{n_a}] \quad (\text{II-71})$$

When Equations (II-63, 68) are added to the system we obtain

$$\dot{x} = \begin{bmatrix} F_2 & | & O_{2 \times 3} & | & O_{2 \times 18} & | & O_{2 \times 2} \\ O_{3 \times 2} & | & A_2 & | & A_3 & | & O_{3 \times 2} \\ O_{18 \times 2} & | & O_{18 \times 3} & | & A_1 + B_1 F_1 & | & O_{18 \times 2} \\ O_{2 \times 2} & | & O_{2 \times 3} & | & O_{2 \times 18} & | & A_4 \end{bmatrix} x + \begin{bmatrix} B_2 \\ O_{3 \times 2} \\ O_{18 \times 2} \\ O_{2 \times 2} \end{bmatrix} u + \begin{bmatrix} O_{2 \times 2} \\ O_{3 \times 2} \\ B_1 G_2 \\ O_{2 \times 2} \end{bmatrix} v_1 + \begin{bmatrix} O_{2 \times 6} \\ O_{3 \times 6} \\ G_1 & | & O_{18 \times 2} \\ O_{2 \times 4} & | & G_3 \end{bmatrix} \eta \quad (\text{II-72})$$

Finally, we substitute for  $v_1$  from Equation (II-64) and perform the matrix multiplications and additions to obtain the complete system equation

$$\dot{x} = \begin{bmatrix} F_2 & | & O_{2 \times 3} & | & O_{2 \times 18} & | & O_{2 \times 2} \\ O_{3 \times 2} & | & A_2 & | & A_3 & | & O_{3 \times 2} \\ B_1 G_2 H_1 & | & O_{18 \times 3} & | & A_1 + B_1 F_1 & | & O_{18 \times 2} \\ O_{2 \times 2} & | & O_{2 \times 3} & | & O_{2 \times 18} & | & A_4 \end{bmatrix} x + \begin{bmatrix} B_2 \\ O_{3 \times 2} \\ B_1 G_2 H_2 \\ O_{2 \times 2} \end{bmatrix} u +$$

$$+ \begin{bmatrix} 0_{2 \times 6} \\ 0_{3 \times 6} \\ \hline G_1 \quad | \quad 0_{18 \times 2} \\ \hline 0_{2 \times 4} \quad | \quad G_3 \end{bmatrix} \eta \quad \text{(II-73)}$$

**System Observation and Control Equations**

The aircraft system states are observed and fed back for display to the pilot through the flight director. The pilot model assumes that the human pilot can perceive both error signal and error signal rate while observing the motion of the flight director command bars. The observation vector then consists of the longitudinal and lateral-directional error commands and their time derivatives as follows

$$y' = [y_L, \dot{y}_L, y_{LD}, \dot{y}_{LD}] \quad \text{(II-74)}$$

The observation equation can then be written as

$$y = \begin{bmatrix} \quad | \quad c_1 \quad | \\ 0_{4 \times 2} \quad | \quad c_2 \quad | \quad 0_{4 \times 12} \\ \quad | \quad c_3 \quad | \\ \quad | \quad c_4 \quad | \end{bmatrix} x \quad \text{(II-75)}$$

# Contrails

where the partition row matrices in Equation (II-75) are defined by Equations (A-70 to A-73)

$$\begin{aligned}
 C_1 &= [\sin\phi_o \quad 0 \quad K_{d_z} \quad O_{1 \times 3} \quad \cos\phi_o \quad O_{1 \times 4}] \\
 C_2 &= [(K_{d_z} U \sin\phi_o) \quad O_{1 \times 3} \quad (-K_{d_z} U) \quad 1 \quad (K_{d_z} U \cos\phi_o) \\
 &\quad O_{1 \times 3} \quad (-\dot{\psi}_o \cos\phi_o)] \\
 C_3 &= [(-K_{\psi} \cos\phi_o) \quad (-K_{d_y}) \quad O_{1 \times 4} \quad (K_{\psi} \sin\phi_o) \quad O_{1 \times 3} \quad (-1)] \\
 C_4 &= [(-K_{d_y} U \cos\theta_o \cos\phi_o) \quad O_{1 \times 5} \quad (K_{d_y} U \sin\phi_o - \dot{\psi}_o) \quad (-1) \\
 &\quad (-K_{\psi} / \cos\theta_o - \tan\theta_o) \quad (-K_{d_y} U) \quad (-K_{\psi} \dot{\psi}_o \sin\phi_o)]
 \end{aligned}
 \tag{II-76}$$

The control Equation (II-1) is then defined for the piloted system problem formulation by the control vector, Equation (II-62), the observation vector, Equation (II-74), and the following H-matrix as defined by Equation (A-79)

$$H = \begin{bmatrix} -K_{P_L} & -K_{P_L}^T L_L & -K_1 & -K_2 \\ -K_3 & -K_4 & -K_{P_{LD}} & -K_{P_{LD}}^T L_{LD} \end{bmatrix}
 \tag{II-77}$$

The additional gains,  $K_1$ ,  $K_2$ ,  $K_3$ , and  $K_4$ , are required by the Heath computer algorithm even though they are not necessarily representative of the actual pilot control

activity. In theory, they can be explained as cross coupling pilot gains between the longitudinal and lateral-directional mode error signals and the opposite mode control actuators.

## System Response Equations

To fully define the mathematical pilot the response vector must be defined in such a manner that it accurately describes the pilot tracking task considering the limitations of the pilot workload and the computational algorithm. For this study the pilot was assumed to be performing a pure tracking task, attempting to minimize the flight director command bar error signal. This assumption dictated that two of the responses be the displayed flight director error signals for the two modes. The computer algorithm also required that two responses include the system control variables. Finally, two additional responses were defined to be the pilot states. These states were included to allow the algorithm to further limit the pilot workload. The response vector was then

$$z' = [x_{P_L}, y_L, u_{P_L}, x_{P_{LD}}, y_{LD}, u_{P_{LD}}] \quad (II-78)$$

The D- and T-matrices of Equation (II-3) then became

$$D = \begin{bmatrix} 1 & 0 & | & O_{1 \times 11} & | \\ 0 & 0 & | & C_1 & | \\ 0 & 0 & | & O_{1 \times 11} & | \\ 0 & 1 & | & O_{1 \times 11} & | \\ 0 & 0 & | & C_3 & | \\ 0 & 0 & | & O_{1 \times 11} & | \end{bmatrix} \quad O_{6 \times 12}$$

$$T = \begin{bmatrix} - & O_{2 \times 2} & - \\ 1 & 0 & - \\ - & - & - \\ & O_{2 \times 2} & - \\ - & - & - \\ 0 & 1 & - \end{bmatrix}$$

(II-79)

where  $C_1$  and  $C_3$  are defined in Equation (II-76).

The response weighting matrix,  $Q$ , is discussed along with the presentation of results.

## RESULTS OF SYSTEM DESIGN AND RESPONSE CALCULATIONS

The stability augmentation design and piloted system response calculations were performed with programs written for the CDC/6600 Cyber 74 computer system. The programs were executed principally in a semi-interactive mode using CDC SCOPE control commands and the EDITOR file editing program via an interactive INTERCOM computer terminal. This method allowed rapid manual adjustment of both the quadratic weights during SAS design and the pilot remnant during the system response calculations. It also allowed manual intervention when convergence problems occurred.

The symbolic system equations, the aerodynamic and thrust data, and the values of the fixed parameters and derivatives are presented in Appendix A. Numerical values for the remaining system parameters, the basic equation coefficients, and the unaugmented system poles are given in this section. The limits on pole variation and control motion are discussed, and the numerical results of the SAS design and system response calculations are presented.

### Trim Parameter Values

The SAS design of this study was conducted at three trim points as defined by available data, primarily from Reference

# Contrails

23. These points were specified by aircraft inboard/outboard flap configuration and airspeed as follows:

<u>Flaps</u> (degrees)	<u>Airspeed</u> (knots, ft/sec)	
98/65	60.	101.3
75/60	75.	126.6
45/30	105.	177.2

All conditions were for wings-level, horizontal flight, except for the 98/65 degree flaps point. This configuration represented a final approach, on glide-slope, condition; thus, a negative 7.5 degree flight path angle was used. The thrust curves for 95 percent propeller rpm from the supplement to Reference 23 were used for all calculations. Subsequent data will be identified by the appropriate inboard flap setting or airspeed.

For these conditions the trim equations described in Appendix A yielded the trimmed values shown in Table 3.1.

Table 3.1

Trim Aerodynamic and Thrust Parameters

Flaps	$\alpha$ (deg)	$C_L$	$\bar{C}_D$	$T'_C$	P/4 (hp)	T/4 (lb)
98	0.216	3.52	.464	.449	368	1220
75	-6.48	2.27	0.	.476	651	2020
45	-3.05	1.16	0.	.116	443	9630

The trim-dependent longitudinal stability derivatives are shown in Table 3.2

Table 3.2

Longitudinal Stability Derivatives

Flaps	$C_{x_u}$	$C_{x_\alpha}$	$C_{z_u}$	$C_{z_\alpha}$	$C_{m_u}$	$C_{x_{\delta_T}}$	$C_{z_{\delta_T}}$	$C_{m_{\delta_T}} \times 10^4$
98	-1.33	1.61	-5.01	-6.85	.0945	.163	-.796	-3.51
75	-.981	.649	-3.83	-8.56	.107	.138	-.202	-1.38
45	-.290	.591	-2.36	-7.72	.0301	.0692	-.0988	-.429

Using these derivatives, the numerical values for the equation of motion matrix coefficients were computed. The appropriate coefficients from the basic A-matrix for the longitudinal mode  $\dot{u}$ ,  $\dot{\alpha}$ ,  $\dot{q}$ , and  $\dot{\theta}$  equations are presented in Table 3.3.

The A-matrix coefficients for the lateral-directional mode  $\dot{p}$ ,  $\dot{r}$ ,  $\dot{\beta}$ , and  $\dot{\phi}$  equations are shown in Table 3.4.

The basic system poles were computed for both the longitudinal and lateral-directional modes. They are given in Tables 3.5 and 3.6. Since the longitudinal short period mode was overdamped for each of the conditions, both the pair of real roots and their equivalent frequency and damping ratio ( $\omega_r$ ,  $\zeta_r$ ) are shown for this mode.

Table 3.5

Unaugmented Aircraft Longitudinal Poles

Flying Quality and Control Surface Limits

Considerable data and experience is available for specification of flying qualities of conventional aircraft. In contrast, data is being accumulated but is less readily available for justifying flying quality specifications for STOL aircraft. A combination of references for both conventional and STOL aircraft was consulted to determine suitable flying quality boundaries for the Breguet 941. The primary source for conventional flying qualities was Reference 18. Reference 24 presents more lenient flying quality boundaries as they have been applied to V/STOL aircraft, and Reference 25 discusses NASA proposals for suitable STOL flying qualities.

The specifications of Reference 25 are applicable to any aircraft in the STOL mode. This mode is defined by operational airspeeds below  $V_{con}$ , which is a conversion speed mutually agreed upon by the aircraft designer and the federal government agency procuring the aircraft. Because of this arbitrary definition both the parameter boundaries from References 24 and 18 are summarized in the following paragraphs.

# Contrails

Reference 19 used all of the applicable conventional aircraft flying quality specifications of Reference 18 in developing a "handling qualities" mode for SAS design. However, that model eliminated the longitudinal phugoid and lateral-directional spiral modes, which were retained in the analysis of this study. In addition, the primary emphasis in this study is to vary the system poles parametrically to investigate gust response, not to develop a specific handling qualities model. The basic aircraft flying qualities had been judged satisfactory or acceptable in the STOL mode,<sup>23</sup> and the variations in this study were constrained to the acceptable region.

From the tables above one can see that all of the basic poles are stable. In addition, the optimal control computer algorithms require initial stable conditions and do not yield unstable solutions. These two characteristics allowed the retention of all modes in the design process. Also, where an unstable system pole was allowed by the specifications the neutral stability boundary was listed as applicable for the purposes of this analysis.

Reference 18 defines 3 levels of flying qualities. Interpreted for this study, the first two levels are ---  
level 1: clearly adequate for the approach and landing task;  
and level 2: some degradation in approach and landing characteristics or increase in pilot workload, or both.  
clearly one would not intentionally design SAS to degrade

performance to level 2 specifications unless other considerations such as gust response were judged to be of overriding importance. However, as a matter of interest and because of the uncertainty about  $V_{con}$  both the level 1 and level 2 limits are listed here.

### Longitudinal Specifications

The longitudinal poles are specified by the short period and phugoid frequencies and damping ratios, and the limits on these parameters are presented in this section.

No restriction was specified for the phugoid frequency, and by definition it will be between (not including) zero and the short period frequency. The restriction on the phugoid damping provided by Reference 18 is  $\zeta_p > .04$ . This limit is well below any of the values that were achieved in this study.

The short period damping ratio limits from References 18 and 24 are as follows:

Trim Point	$\zeta_{sp_{min}}$			$\zeta_{sp_{max}}$	
	$V < V_{con}$	Lev. 2	Lev. 1	Lev. 1	Lev. 2
All	0.	.25	.35	1.30	2.0

The short period frequency limits were determined by first calculating the ratio

$$n/\alpha = -(U/g) Z_w = -(Sq)/(mg) C_{Z_\alpha} \quad (III-1)$$

The limits were then found from the appropriate figures in the two references. These limits are as follows:

# Contrails

Trim Flaps	n/α	$\omega_{sp_{min}}$			$\omega_{sp_{max}}$	
		V < V <sub>con</sub>	Lev. 2	Lev. 1	Lev. 1	Lev. 2
98	1.93	.54	.60	----	---	4.1
75	3.77	.75	.60	.87	3.7	6.1
45	6.66	---	.80	1.03	4.9	8.2

The value of n/α for the 98 degree flap point (60 knots) was below the level 1 boundary. No limit is listed for V < V<sub>con</sub> for the 45 degree flap point since the 105 knot air-speed is most probably above any reasonable V<sub>con</sub> that would be adopted.

## Lateral-Directional Specifications

The lateral-directional poles are defined by the dutch roll frequency and damping ratio, the roll mode time constant, and the spiral mode time to double or one-half amplitude. The boundaries on these parameters are summarized in this section.

The specifications require that there be no coupling between the roll and spiral modes; the roots must be real. Reference 24 requires, in addition, that all real roots be stable; thus, the roll time constant is finite. The more restrictive level 1 and level 2 limits on the roll time constant from Reference 18 are  $T_{R-} < 1.0$  and  $T_{R-} < 1.4$ , respectively.

Reference 24 requires, also, that the real spiral mode pole be stable. Since all roots in this analysis were stable the only limit on the spiral mode was the limit on the time-to-one-half-amplitude constant,  $T_{\frac{1}{2}}$ . If the spiral

mode is too stable, constant control force will be required during steady turns --- an objectionable flying quality. Reference 25 presents pilot flying quality ratings as a function of spiral stability. In that study an optimum value of  $T_{\frac{1}{2}} = 20$  seconds was selected. Van Dierendonck<sup>19</sup> suggests an upper bound on spiral stability of  $T_{\frac{1}{2}} = 10$  seconds. The corresponding spiral poles for these two values of  $T_{\frac{1}{2}}$  are  $(-1/T_S) = -.0346$  rad/sec and  $(-1/T_S) = -.0693$  rad/sec, respectively.

The dutch roll frequency and damping ratio are bounded by minimum values as follows:

$$\omega_{d_{\min}} = .25 \text{ rad/sec (V < V}_{\text{con}}); .4 \text{ rad/sec (lev. 2);}$$

$$1.0 \text{ rad/sec (lev. 1)}$$

$$\zeta_{d_{\min}} = 0. \text{ (V < V}_{\text{con}}); \left\{ \begin{array}{l} \zeta_d \geq .02 \\ \zeta_d \omega_d \geq .05 \end{array} \right\} \text{ (lev. 2);}$$

$$\left\{ \begin{array}{l} \zeta_d \geq .08 \\ \zeta_d \omega_d \geq .15 \end{array} \right\} \text{ (lev. 1)}$$

where the condition yielding maximum  $\zeta_d$  is to be selected for each level.

### Airspeed and Control Surface Limits

In addition to the flying quality boundaries presented above, there exist the physical constraints on airspeed to avoid stalls and the structural limits on control surface motion. Because of the linearized analysis employed in this

# Contrails

study no constraints on airspeed or control motion were included in the computer algorithm. Thus, the validity of each system response calculation had to be judged aposteriori by comparing the airspeed and control surface variations with the boundaries on these variables.

Reference 25 presents the operational envelope for the Breguet 941 in landing configuration (98 degree flaps) for steady-state flight. Although the system response in turbulence does not imply steady-state flight, the steady-state envelope does provide an estimate for the airspeed limits. The minimum airspeed from Reference 25 is approximately 40 knots at maximum power or 53 knots at the approach power setting, and the maximum airspeed is the maximum flaps extended speed of 80 knots. Thus, a potential 20 knot variation about the 60 knot trim point could be achieved. The validity of a linear solution would most certainly be in question if such a variation were actually experienced. A more reasonable variation would be the 7 knots maximum variation at constant power.

The throttle control derivatives were normalized in such a manner that the throttle variation was constrained between the approximate limits of zero and one, or  $\pm 0.5$ . If the trim throttle setting is nearer idle or full power these limits are reduced accordingly.

Reference 25 states the limits on the elevator, aileron, and rudder deflections as follows:  $-24 \text{ deg} \leq \delta_e \leq 30 \text{ deg}$ ,  $|\delta_a| \leq 34 \text{ deg}$ , and  $|\delta_r| \leq 40 \text{ deg}$ .

# Contrails

To provide 99.74 percent confidence that each variance will not exceed its limit the three-sigma (standard deviation) level is equated to the limit. If this is done the maximum values for the standard deviations (rms errors) of the controls are  $\sigma_{\delta_{e_{\max}}} \approx 0.14$  rad.,  $\sigma_{\delta_{a_{\max}}} \approx 0.20$  rad.,  $\sigma_{\delta_{r_{\max}}} \approx 0.23$  rad. Obtained in a similar manner, the maximum rms normalized airspeed error at the 98 degree flap trim point is  $\sigma_{\underline{u}_{\max}} \approx 0.039$ . And the maximum rms throttle error is  $\sigma_{\delta_{T_{\max}}} \approx 0.17$  rad.

## SAS Design Results

Initial attempts were made in this study to design Breguet 941 stability augmentation systems (SAS) using so called "classical" methods outlined by Blakelock.<sup>22</sup> Such frequency analysis methods (principally root locus) can handle only single-input/single-output systems. One loop at a time is closed, and if the SAS contains multiple loops either an iterative procedure or considerable design experience must be employed in order to achieve the desired pole placement. In addition, the majority of the SAS modes described by Blakelock (e.g., pitch attitude control, pitch rate damping, pitch orientation control, velocity control, sideslip coordination, and yaw orientation control) can be reduced to various combinations of incomplete pure state feedback with at most a few added states for washout filters in the circuits. It was difficult to use these methods to

achieve significant variation in the system poles, and especially to make a systematic pole variation.

An alternate approach using the optimal incomplete feedback computer algorithm and rate-model-in-the-performance-index method was found to be much more suitable for the purposes of this study. The details of the method are discussed in the previous chapter and in Appendix B. This method provides good pole placement, low feedback gains, and as shown in Reference 19, the time response of the augmented system closely matches that of the model. The method is quite flexible in that the rate-model can be adjusted arbitrarily, e.g., to satisfy handling qualities criteria or to provide decoupled response modes. In addition, the quadratic weights in the performance index can be adjusted to restore the servo-actuator poles arbitrarily near to their unaugmented values.

Using this method a set of poles was specified, and the rate-model coefficient matrix was calculated. Then a set of quadratic weights was found by trial and error to provide convergence for the SAS design algorithm. Once convergence was achieved the quadratic weights were adjusted further until good servo pole placement was achieved. Once a set of quadratic weights was found for a given trim condition and feedback set, a large variation in poles could be made without having to re-adjust the weights. This allowed efficient and rapid SAS design for parametric pole variation.

# Conclusions

Two other problems often encountered in gradient computer algorithms are the choice of stable starting feedback gains and the achievement of rapid convergence to the solution. Both of these problems were minimized in this study because of the stability of the unaugmented system and the use of the gradient transformation to equivalently circularize the performance functional. The same starting gains were used for all SAS designs. These consisted of zero gains on all states except for the stochastic disturbance states which were fed back with unit starting gains to properly initiate the algorithm.

In order to provide a stochastic disturbance model with bandwidth similar to the gust disturbances the break frequencies of the command inputs were defined as follows:

$$\omega_{c_e} = U/L_w, \quad \omega_{c_T} = U/L_u, \quad \omega_{c_a} = \pi U/(4b), \quad \text{and} \quad \omega_{c_r} = U/L_v.$$

Several combinations of full and partial state feedback SAS designs were tried, including washout filters on pitch attitude in the longitudinal mode and the roll attitude and yaw rate in the lateral-directional mode. Investigation of the washout filters was inspired by two considerations. First, practical SAS will include some washouts to allow the pilot to maneuver the aircraft and maintain steady non-zero values of the washed out variables, e.g., a steady pitch attitude or bank angle. Second, the "gust-proofed" SAS for the DC-8 aircraft in Reference 17 used lag-lead compensation

# Contrails

for gust alleviation. Because of the mode of the partial state feedback in this study, the lag-lead circuits could be approximated by adding lag (washout) states to the SAS design system model.

For the lateral-directional mode the washout equations were

$$\begin{aligned}\dot{x}_1 &= -(0.1)x_1 + \dot{\phi} \\ \dot{x}_2 &= -(0.1)x_2 + \dot{r}\end{aligned}\tag{III-2}$$

The break frequency (0.1 rad/sec) was chosen after a few trials, and little effort was made to optimize it.

Equations (II-10) and (II-28) define the full state feedback observation vectors. Feedback of each stochastic control disturbance state and each servo-actuator state for the two modes is required by the algorithm when the SAS mode involves that control. Choice of the remaining feedback states is arbitrary, but practical problems were encountered for partial state feedback modes attempted in this study. Some SAS design was attempted for the lateral-directional mode without sideslip and bank angle feedback. For this feedback mode it was difficult both to achieve solution convergence and to obtain good pole placement. It was particularly difficult to restore the servo poles to their unaugmented values. Because of these problems the majority of the SAS design was done with the full observation vectors of Equations (II-10) and (II-28).

# Contrails

Van Dierendonck<sup>19</sup> suggests that additional responses can be added to the basic rate-model performance functional to satisfy specific SAS design requirements. However, he states that the final design with added response equations will be a compromise between the specified rate-model flying qualities and the additional requirements.

The Breguet 941 has a disturbing cross-coupling between the lateral and directional modes such that small bank angle changes produce large yaw rate and sideslip excursions.<sup>25</sup> Thus, it is natural to include the sideslip angle as a separate response variable in order to minimize these excursions in the augmented aircraft. This SAS design was accomplished, but as predicted the most significant result was that the augmented system poles were shifted as the quadratic weight on the sideslip response was increased proportionately. As might have been expected the primary change was an increase in the dutch roll frequency and some change in the damping. Essentially the same results were achieved merely by parametric pole variation using the basic rate model; thus, the sideslip response SAS design mode was discarded as redundant for this study.

As shown in this chapter, the unaugmented system poles lie within the acceptable flying quality boundaries for conventional aircraft with three exceptions. The value of  $n/\alpha$  for the 98 degree flap trim point (60 knots) places the short period pole within the level 2 region; and the dutch

# Contrails

roll frequencies for both the 60 knot and 75 knot trim points are slightly below the level 1 boundary but within the level 2 region. The 60 knot airspeed most certainly would be considered within the STOL range, and the 75 knot airspeed could possibly qualify, also.

Pilots who flew the Breguet 941 rated the longitudinal handling qualities satisfactory and only expressed dissatisfaction with the lateral-directional flying characteristics. The variation in gust response in this study was found to be an order of magnitude greater for the lateral-directional mode as compared to the longitudinal. Thus, the majority of the parametric pole variation SAS design was concentrated on this mode. Also, the pole placement algorithm achieved good results for all four lateral-directional poles and for the longitudinal short period mode, but the phugoid poles could not be varied systematically, even after considerable experimentation with the quadratic weighting matrix. The longitudinal poles for the SAS designs which were accomplished are shown in Table 3.7.

The pilot longitudinal control strategy using elevator (only) proved to be satisfactory for the 75 knot and 105 knot trim points, but difficulty was encountered at the 60 knot trim speed. For this point in order to calculate the system response at all it was necessary to use both the elevator and throttle in the SAS design. Even with this type of SAS no system poles were found which provided acceptable gust

Table 3.7

response levels for all system states and controls.

It is appropriate to comment on these two problems at this point. The difficulty in placing the phugoid poles was most probably a fault in the longitudinal pole placement algorithm complicated by at least two factors. First, the short period and phugoid poles are not as distinctly separated as the lateral-directional mode poles. Second, with the large flap deflections in the STOL mode, a change in throttle setting not only changes the thrust and longitudinal force balance but also produces an even larger change in lift. This fact is evident from the control derivatives

$C_{X_{\delta t}}$  and  $C_{Z_{\delta t}}$  in Table 3.2. An optimal control SAS design method exists by which all of the poles can be placed exactly; i.e., by using a single control and the phase variable (transform) form. However, that method yields large feedback gains, in general. It could be used for further study of the longitudinal mode problems. The second problem, excessive longitudinal mode gust response at 60 knots, was most probably due to the simplified flight director used for this study, and to the pilot control strategy. The airspeed feedback to the throttle was limited to pole placement and not necessarily to maintaining a constant airspeed. Improved airspeed performance could be achieved by either a separate outer loop auto throttle or by allowing the pilot to adjust the throttles.

The variation in the lateral-directional dutch roll pole is shown in Figures 3.1 through 3.3. The range in dutch roll frequency was extended down well below the level 1 flying quality boundary for 60 knots and 75 knots in order to establish the basic response trends. Since there are no upper boundaries on dutch roll frequency in the specifications the upper limit was also chosen as the point above which the gust response trends were readily apparent. Figures 3.1 through 3.3 provide an assessment of the SAS design pole placement accuracy. The intersections of the solid lines represent dutch roll frequency and damping values specified in the rate-model, while the symbols show the actual design values.

Figure 3.1  
Augmented Dutch Roll Poles, 60 Knots

Figure 3.2  
Augmented Dutch Roll Poles, 75 Knots

Figure 3.3  
Augmented Dutch Roll Poles, 105 Knots

The roll and spiral mode poles were also varied for the lateral-directional case. The spiral mode stability was increased up to the limiting value of  $T_{\frac{1}{2}} = 10$  seconds. Since there was no lower limit specified on the roll time constant the roll pole stability was increased until either the system gust response no longer changed or until the roll and servo-actuator poles became coupled.

Most of the lateral-directional SAS design for the 105 knot trim point was generated with quadratic weights yielding servo poles near the following values: -42.8 rad/sec and -7.6 rad/sec. For reference, one set of SAS designs was accomplished with servo poles restored nearer to the unaugmented values: -12.6 rad/sec and -8.9 rad/sec. These servo poles do have a significant effect upon gust response as shown later.

It was possible to reduce servo pole shift using a diagonal weighting matrix. However, to completely restore the poles and eliminate actuator cross-coupling it may be necessary to use off-diagonal quadratic weights.

SAS design feedback gains for selected poles are presented in Table 3.8. The corresponding quadratic weights are also shown. The lateral path error for these poles is shown in Figure 3.14.

### Flight Director Design

Other studies have been conducted to design optimum flight directors, and their results could have been applied

in this analysis. In theory, each SAS design would dictate a different flight director system in order to achieve the true optimum overall system response. However, in order to reduce the design effort a very simple flight director system was chosen, and the gains were held constant for all SAS designs. A valid comparison of the results was still considered to be possible under these conditions.

The flight director equations were presented in Chapter II. In the longitudinal mode the only feedback states were pitch angle and vertical path error. In the lateral-directional mode the feedbacks were bank angle, yaw angle, and lateral path error. Working with the unaugmented system, initial gains were selected to stabilize the full piloted system with the assistance of classical frequency analysis tools. Then, in order to adjust the gains to suit the Breguet 941, one set of calculations was made using the Heath computer algorithm. For these runs the problem was reformulated to introduce the flight director gains into the system feedback gain matrix, H. For example, for the longitudinal mode a new observation vector,  $y_2 = C_o x$ , was defined, where

$$y_2' = [\theta, d_z, \dot{\theta}, \dot{d}_z] \quad (\text{III-3})$$

The control then was expanded and new gain and observation matrices were defined.

$$u = -Hy = -HCx = -HC_1 C_o x = -H_1 y_2 \quad (\text{III-4})$$

# Contrails

where

$$\begin{aligned} -H_1 = -HC_1 &= [K_p \quad K_p^T L] \begin{bmatrix} 1 & K_{d_z} & 0 & 0 \\ 0 & 0 & 1 & K_{d_z} \end{bmatrix} \\ &= [K_p \quad (K_p K_{d_z}) \quad (K_p^T L) \quad (K_p^T L K_{d_z})] \end{aligned} \quad (\text{III-5})$$

and  $C_0$  was defined such that  $C = C_1 C_0$ . This problem formulation could have been used to optimize pilot and flight director gains simultaneously for each SAS design, but the decision was made to fix the flight director in order to better isolate the effects of the varying SAS parameters. The reduced number of system gains to be calculated also decreased the computer solution time.

The gains computed for all of the trim points were sufficiently close that the same values were used for all conditions, except for the lateral-directional mode for 60 knots. The final gains are shown in Table 3.9.

Table 3.9

### Flight Director Gains

Trim Flaps (deg)	$K_{d_z}$ (rad/ft)	$K_\psi$ (rad)	$K_{d_y}$ (rad/ft)
98	.008295	.20004	.00022880
75	.008295	.3701	.00028427
45	.008295	.3701	.00028427

## Pilot Model

The quadratic optimal pilot model worked well for nearly all SAS designs attempted in this study. The pilot gains were reasonably consistent, and in particular, the pilot lead equalization was always below one second. After some experience the remnant convergence could be achieved rapidly. The remnant parameters as determined from Reference 17 were computed to be  $\omega_{R_e} = .7143$  rad/sec,  $\omega_{R_a} = .7407$  rad/sec,  $K_{R_e} = .05669$ , and  $K_{R_a} = .1016$ . These values are based upon the similarity between the tracking tasks in this study and that of Reference 17. The pilot scanning behaviour includes typical instrument scanning patterns and dwell fractions plus a 22 percent margin. The pilot time delay was also chosen to conform to the scanning behaviour of Reference 17. The value used was  $\tau = 0.3$  sec.

As stated in the previous chapter, the complete pilot model includes the quadratic optimal performance functional, involving the weighting matrix, Q. As shown in the cited references on optimal pilot models (References 5 through 8) the quadratic weights along with other model parameters can be used to match the mathematical model to simulator or actual flight pilot tracking data. Once matches are made to several sets of data an engineer can begin to have confidence in using the model to make predictions about the actual performance of a pilot in a new aircraft or a new task.

In the absence of actual or simulated tracking data for STOL aircraft the selection of quadratic weights was made in this study on the basis of engineering judgement of reasonable pilot and system performance. A limited number of runs were made to investigate the effect of varying quadratic weights. Bode plots of the pilot open loop transfer function for both the lateral-directional roll tracking task and the complete lateral-directional flight director command tracking task are shown in Figures 3.4 and 3.5 for two sets of quadratic weights. Table 3.10 gives the system response and pilot gains for these two pilot models: models 1 and 2. In addition, the system response was calculated without any pilot remnant disturbance, and these results are shown for comparison, model 3.

Table 3.10

System Response for Various Pilot Models

Model	<u>Pilot Parameters</u>					
	$\sigma_u$	$K_p$	$T_L$	$q_{x_p}$	$q_y$	$q_{u_p}$
1	.0286	.440	.967	1.	1.	1.
2	.0796	1.50	.626	1.	100.	1.
3	0.	1.28	.751	1.	100.	1.

Model	<u>Responses</u>						
	$\sigma_\psi$ (rad)	$\sigma_{d_y}$ (ft)	$\sigma_p$ (rad/ sec)	$\sigma_r$ (rad/ sec)	$\sigma_\beta$ (rad)	$\sigma_\phi$ (rad)	$\sigma_{\delta_a}$ (rad)
1	.0760	110.	.0447	.0457	.0629	.0556	.0274
2	.0613	64.5	.0703	.0480	.0643	.0389	.0694

From the Bode plots one can see that either set of quadratic weights yields a pilot model with the negative 20 decibel per decade logarithmic magnitude slope at the open loop unit gain cross-over frequency. The phase margins are also quite adequate. The model with unit quadratic weights has lower pilot gain, lower cross-over frequency and as expected poorer path tracking performance. However, the pilot lead is larger. The higher weighting on the tracking error,  $q_y = 100.$ , was chosen for the system response calculations in this study. However, it appears that the lower quadratic weight,  $q_y = 1.$ , yields results that are more nearly comparable to the results in Reference 10.

For the unaugmented system in this case the remnant increased the path tracking error by about 20 percent. The relative weighting on the system control could also be adjusted to fit the model to actual tracking data. In the absence of this data the results of this study must be assessed on a relative basis as showing general trends in the system response rather than absolute values of the tracking performance.

### System Response Results

The gust response of the piloted system was calculated for each of the SAS designs described previously, assuming wings-level flight. For this case the longitudinal and lateral-directional modes decoupled, and the response of each mode could be computed separately. In addition to the

wings-level cases the banked flight system response was computed for two sets of SAS gains for bank angles up through 30 degrees. The results of these calculations are shown in this section.

The gust response of the longitudinal mode was found to be an order of magnitude less than the lateral-directional, and the variation with SAS gains was also less significant. The longitudinal mode response is shown in Table 3.11. Except for the 60 knot trim point the best response for any SAS design was for the unaugmented system. As the short period frequency was increased for the 75 and 105 knot cases the vertical tracking error increased.

A set of pilot gains could not be found to stabilize the longitudinal mode for the unaugmented system at 60 knots. Of the SAS designs accomplished for this case the one with short period frequency and damping  $\omega_{sp} = 1.0$  rad/sec and  $\zeta_{sp} = .90$  was the design with the most nearly acceptable system response. Only the rms airspeed error is greater than the acceptable limits for this case.

The wings-level lateral-directional system response is listed in Table 3.12. Both the augmented system poles and the rms responses are shown. The cases are grouped respectively by trim point, roll and spiral mode poles, dutch roll damping ratio, and increasing dutch roll frequency. The rms lateral tracking error for these cases is plotted in Figures 3.6 through 3.16.

# Contrails

One can see immediately from the lateral error plots that the variation in SAS design has a large effect upon the piloted system lateral gust response. For the range of poles in this study the lateral tracking error varied about 50 percent above and below the value for the basic unaugmented aircraft. As might have been expected the same general trends in the response are exhibited at each of the three trim points. For fixed roll and spiral poles and dutch roll damping the lateral path error increases with dutch roll frequency. A notable exception to this general trend is exhibited at the 105 knot trim point. For this case there appears to be a distinct minimum in the response curves near the frequency  $\omega_d = 1.2$  rad/sec as can be seen in Figures 3.11 through 3.14 and 3.16. Increased dutch roll damping also appears to increase the lateral path error, except for two sets of data at the 105 knot trim point, Figures 3.11 and 3.12, where the curves for the three damping ratios are almost superimposed. For these cases the basic spiral pole was used.

In contrast, an increase in stability of either the spiral or roll mode poles improved the lateral tracking error. In fact, a considerable reduction in lateral path error was achieved by shifting the roll mode pole out from the origin for the low dutch roll frequencies. The lateral error is plotted versus the roll mode pole for the three trim points in Figures 3.8, 3.10, and 3.15. Reference 25 notes that roll

augmentation is a desirable means for providing good lateral handling qualities while at the same time allowing the basic airframe to remain insensitive to gusts. The results of this study confirm that. However, from these three figures it can be seen that the gust response curves level off eventually, limiting the gust response improvement that can be obtained. Also, a few SAS designs indicated that the improvement is less at higher dutch roll frequencies.

The fourth curve in Figure 3.14 shows the gust response for the SAS cases where the servo poles were restored nearer to their unaugmented values. There is a small change in gust response due to these servo poles over most of the range in dutch roll frequency, but below the minimum response point the difference is quite large.

The system response for the washout filter SAS designs are shown in Table 3.13. Compared to corresponding cases in Table 3.12 some of the washout filter designs provide some improvement in lateral tracking error, while for others the results are worse. The washout SAS designs were not investigated sufficiently to conclude whether they could make a significant improvement for SAS designs involving almost complete state feedback. However, actual applications employing washouts should not significantly degrade gust response.

The flying quality specifications, e.g., Reference 18, specify limits on the maximum sideslip excursions which can result during a rudder-pedals-free aileron induced roll. Due

to the nature of the manual roll tracking task in this study, where the pilot is controlling with aileron (only), the rms sideslip error should provide a similar measure of flying qualities. For this reason the rms sideslip error for one set of SAS designs at the 105 knot trim point (the same cases as for Figure 3.14) are plotted in Figure 3.17. These curves show that the sideslip error is relatively independent of dutch roll damping. However, the error decreases rapidly, representing significantly improved flying qualities, as the dutch roll frequency is increased. Unfortunately, this conflicts with the optimum lateral path tracking gust response requirements. From these results it appears that the designer must compromise, to some extent, the good conventional flying qualities in order to optimize the path tracking performance in turbulence.

Figures 3.18 and 3.19 show rms response values versus bank angle for one SAS design at 105 knots. The unaugmented longitudinal poles were used, but the lateral-directional SAS provided the following augmented poles. Servo poles =  $(-12.6, -8.87)$ ,  $\omega_d = 1.20$  rad/sec,  $\zeta_d = .287$ ,  $1/T_R = 2.55$  1/sec,  $1/T_S = .0699$  1/sec. For this case both vertical and lateral path errors increased with bank angle.

Figures 3.20 and 3.21 show rms response values versus bank angle for another SAS design. Again the unaugmented longitudinal poles were used. The lateral poles were as

Figure 3.17

# Contrails

follows. Servo poles =  $(-13.0, -8.82)$ ,  $\omega_d = 2.95$  rad/sec,  $\zeta_d = .356$ ,  $1/T_R = 2.57$  1/sec,  $1/T_S = .0695$  1/sec. The main difference in this case is the much higher dutch roll frequency. Again the longitudinal response increased with bank angle, but the lateral path error decreased with bank angle.

These two isolated SAS cases indicate that a smaller but significant variation in gust response also results as bank angle changes, and for banked flight as for level flight, the response trends exhibited by each SAS design are a function of the specific augmented poles.

In Figures 3.6 through 3.16 the rms lateral path error was plotted versus the augmented dutch roll or roll convergence pole. Since the model-matching SAS design method varies the augmented system numerator roots (zeros) as well as the poles one would naturally ask how much of the system response variation is due to zero shift and how much to pole shift. In order to answer this question, one set of SAS designs was made using a single control (rudder) and the phase variable form of the system equations. By this method the zeros were held constant while only the poles of the system were varied. The data for the lateral-directional mode at 105 knots was used and the dutch roll frequency was varied as in Figure 3.11. The resulting rms lateral path error variation was almost identical to that of Figure 3.11 (within one foot); thus, one must conclude that the augmented pole

locations are the determining factor in the piloted system gust response. If the phase variable method were extended to attempt to place all of the poles using rudder (alone) the feedback gains would be excessively large.

In order to illustrate, to some extent, why the system gust response increased as dutch roll frequency was increased a plot of the power spectral density due to sideslip gust disturbance is shown in Figure 3.22. As shown in this figure the power spectrum is reduced significantly in the region near the dutch roll frequency as this frequency is increased from  $\omega_d = 1.2$  rad/sec to 2.95 rad/sec. However, at the same time, the power spectrum curve is increased more rapidly at all lower frequencies due to the total closed-loop piloted system poles and zeros. Similar plots of the power spectrum for the roll gust disturbance did not vary significantly with dutch roll frequency.

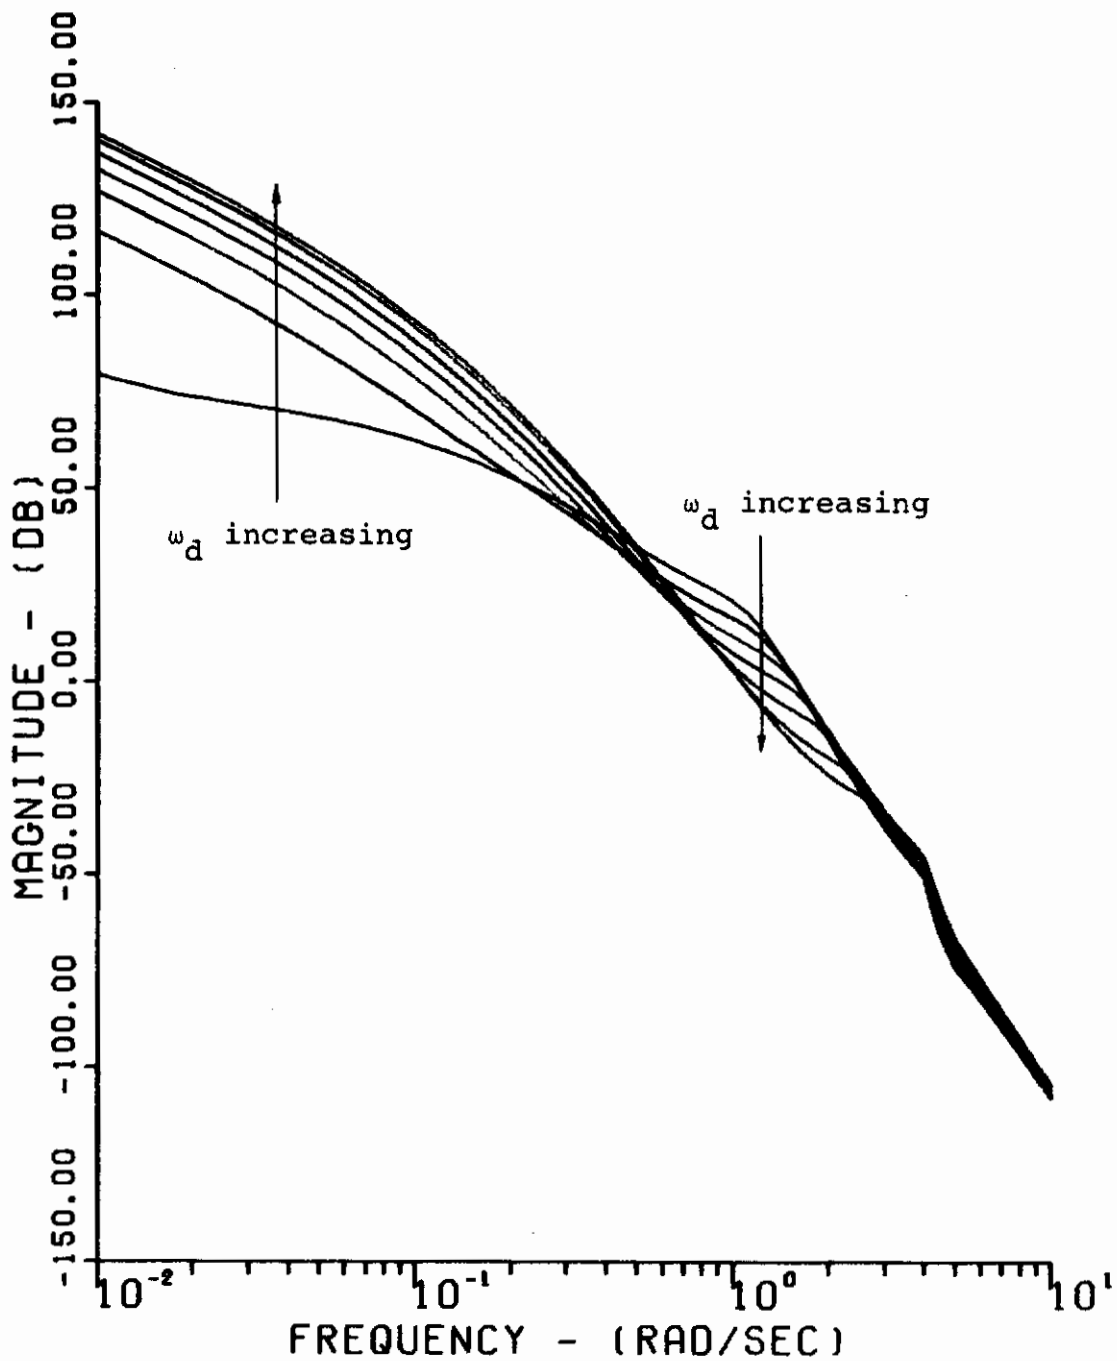

Figure 3.22

Power Spectral Density Plots of the Lateral Path Error for Various Dutch Roll Frequencies from Figure 3.14 ( $\omega_d=1.2, 1.33, 1.49, 1.69, 1.98, 2.47, 2.95$ ),  $\zeta_d=.29$ , Servo Poles =  $(-12.6, -8.9)$

## SUMMARY AND CONCLUSIONS

MLS and other navigational aids will provide new capabilities for multiple aircraft curved precision approach paths, the utility of which must be evaluated and optimized for most efficient air terminal operations. These multiple approach conditions pose new cross track as well as along track separation problems which are influenced by aircraft path tracking precision. Atmospheric turbulence is a significant factor affecting precision tracking, and the augmented system open loop poles have a significant effect upon system gust response. In this study the open loop system poles were varied using SAS and the effect of these poles on manually piloted system gust response was analyzed.

The complete system state-vector equations for the Breguet 941 STOL aircraft, flight director, stability augmentation system, pilot model, and gust model were derived in Appendix A. These equations were linearized for wings level and banked flight trim points. The Dryden gust model for severe turbulence at a 100 ft altitude was used. In order to isolate the effects of gust the mean wind was assumed zero.

A computer algorithm for solving the optimal incomplete feedback control problem for infinite time linear stochastic systems was reviewed in Appendix B, and a convenient method

for frequency analysis of systems in state vector form was described in Appendix C. The main computer programs for this study were listed in Appendix D.

The parametric gust response study was reduced to two optimal incomplete feedback control problems as outlined in Chapter II: (1) to calculate SAS gains for specified open loop poles, and (2) to calculate the pilot gains and system response for these augmented systems. To perform the parametric pole variation in this study the rate-model-in-the-performance-index algorithm for SAS design was converted to a pole placement algorithm. The SAS designs consisted of pure state feedback of the pitch and roll attitudes, pitch, roll, and yaw rates, and linear velocities to the four controls --- elevator, throttle, aileron, and rudder.

A simple two-axes quadratic optimal pilot model was used to provide the pilot compensatory tracking of the flight director command vertical and lateral path error signals. The pilot nulled these error signals by elevator and aileron command inputs. The model of the pilot included both a linear compensatory tracking element having gain, lead, and delay terms and a non-linear remnant term consisting of a first order filtered stochastic disturbance with gain proportional to the rms level of the path error signal.

The results of the parametric SAS design and system response calculations were presented in Chapter III. As a first task, a range of acceptable poles for the decoupled

longitudinal and lateral-directional modes was determined from conventional and STOL flying quality specifications. Then, the open loop poles were varied over this range. Parametric pole variation was accomplished separately for three Breguet 941 flap configurations at corresponding approach speeds. The SAS pole placement algorithm worked quite accurately for all four of the lateral-directional mode poles, including the stable spiral pole, and for the longitudinal short period poles. However, the longitudinal phugoid poles could not be placed successfully with the algorithm. The SAS gains which were computed were never "high gain" but were usually of the order of magnitude of unity, or less.

Frequency analysis of the pilot model gains showed that the model provided results which were reasonable when compared to analytical-verbal frequency models. The open loop cross-over occurred in the region of -20 dB/decade logarithmic amplitude slope with reasonable cross over frequency and phase margins. However, in the absence of actual pilot tracking data the quadratic weights in the performance index were selected arbitrarily. Various values of the weights altered the rms path error significantly; thus, the system response results in this study must be considered as relative values, subject to actual experimental validation.

The vertical rms path errors were an order of magnitude less than the lateral rms path errors. This result was consistent with previous reports that the longitudinal flying

# Conclusions

qualities of the basic aircraft were rated better than the lateral-directional. However, even with the form of SAS which used both elevator and throttle, no SAS gains could be found for the 98 degree flap (60 knot) trim point which could provide acceptable gust response. Either the rms control motion or rms airspeed errors were too large for each design. This indicates a requirement for an outer-loop auto throttle or for the pilot to control flight path manually with both the throttle and elevator. For the 75 degree flap and 45 degree flap points the rms vertical path error increased as the short period frequency was increased. The best gust response was obtained for the basic unaugmented aircraft poles at these trim conditions.

The change in system gust response was most significant for the lateral-directional mode parametric pole variations. For the SAS designs performed in this study the rms lateral path tracking error varied from approximately 50 percent above to approximately 50 percent below that of the unaugmented aircraft. The lateral error increased most significantly with dutch roll frequency and to a lesser degree with dutch roll damping. The lateral error also decreased significantly with increased stability of the roll and spiral mode poles. The spiral stability was limited to avoid handling quality degradation during turns, but the roll stability was increased until no further lateral response improvement was achieved or until roll and servo state

# Conclusions

coupling occurred. Increased roll stability reduced the lateral error by almost 50 percent relative to the unaugmented response. There was also a smaller but significant variation in the lateral error due to a shift in the servo actuator poles.

The disturbing cross-coupling between lateral and directional modes was reduced significantly by an increase in dutch roll frequency. However, this conflicted with optimum gust response, and a tradeoff between conventional flying qualities and gust response must be made by the control system designer.

There was also a significant variation in rms path error as the aircraft was banked into tighter turns. As for the wings level cases, the magnitude and direction of the variation for banked flight depended upon the specific augmented poles.

The large decrease in lateral path error with roll stability suggests that gust response of STOL aircraft should be considered during the basic airframe design phase. In this particular case the roll gust sensitivity of the basic airframe could be further reduced by relaxing the requirement on basic roll stability. Roll stability augmentation could then be used to further reduce lateral tracking error while providing adequate conventional roll flying qualities.

In conclusion, the analysis of this study provided the following principal results:

# Conclusions

(1) the rate-model-in-the-performance-index SAS design algorithm produced good low-gain feedback designs which provide accurate pole placement over a wide range of the acceptable flying qualities region for a STOL aircraft;

(2) the quadratic optimal pilot model calculated reasonable pilot gains and provided a rapid and efficient method for analyzing the system response to atmospheric turbulence;

(3) the rms lateral path tracking error was an order of magnitude greater than the vertical path error;

(4) the variation in augmented lateral-directional mode poles produced a large (plus or minus 50 percent) variation in the lateral path error, and this error could be cut in half primarily by increasing augmented roll stability;

(5) the requirements for reduced lateral and directional mode coupling and optimum gust response conflicted, and a tradeoff must be made by the control system designer.

In using the results of this study the following limitations and recommendation should be considered. The physical bounds on the control motion or airspeed were exceeded for several sets of augmented poles for the longitudinal mode trim points. In addition, rms values of a number of the states in this study were sufficiently large that the assumptions of linearity may have been violated. It would be desirable, then, to validate the results of this study with a simulation in which such factors as the non-linear acceleration terms in the equations of motion, limited SAS

# *Contrails*

authority, control surface and throttle limits, and actual pilot tracking behaviour could be included.

## Appendix A System Equations

The system analyzed in this study was described by a set of stochastic differential equations. The elements of this system were the basic rigid-body aircraft, the servo actuators for the control surfaces, the displacement from the MLS reference flight path, the flight director, the human pilot, and the stability augmentation system. This system was driven by two sets of stochastic inputs: the atmospheric turbulence and the pilot remnant.

This appendix presents the equations describing this stochastic system and its disturbance inputs. A derivation of these equations is outlined and a discussion of the basic assumptions is presented. The source of aerodynamic and thrust data used for the aircraft equations is listed.

### Aircraft Equations of Motion

In this section the linearized small perturbation equations of motion for the basic aircraft and its control surfaces are developed for the two specialized trim conditions considered in this analysis. The aircraft is assumed to be a constant mass, rigid body, symmetrical about its body axes x-z-(vertical) plane. The flat stationary earth

is assumed to be the inertial reference frame.

The full non-linear six-degree-of-freedom force and moment equations under these assumptions are given in Reference 22 as follows

$$\begin{aligned}F_x &= m(\dot{U} + WQ - VR) \\F_y &= m(\dot{V} + UR - WP) \\F_z &= m(\dot{W} + VP - UQ)\end{aligned}\tag{A-1}$$

$$\begin{aligned}L &= \dot{P}I_{xx} - \dot{R}I_{xz} + QR(I_{zz} - I_{yy}) - PQI_{xz} \\M &= \dot{Q}I_{yy} + RP(I_{xx} - I_{zz}) + (P^2 - R^2)I_{xz} \\N &= \dot{R}I_{zz} - \dot{P}I_{xz} + PQ(I_{yy} - I_{xx}) + QR I_{xz}\end{aligned}\tag{A-2}$$

The aircraft attitude is determined by the additional three Euler-angle equations, Equations (1-34a), Reference 22

$$\begin{aligned}\dot{\theta} &= Q\cos\phi - R\sin\phi \\ \dot{\phi} &= P + Q\sin\phi\tan\theta + R\cos\phi\tan\theta \\ \dot{\psi} &= Q\sin\phi/\cos\theta + R\cos\phi/\cos\theta\end{aligned}\tag{A-3}$$

# Contrails

The inverse relations for the body angular rates are easier to linearize. These are (Equations 1-34, Reference 22)

$$\begin{aligned}P &= \dot{\phi} - \dot{\psi} \sin \theta \\Q &= \dot{\theta} \cos \phi + \dot{\psi} \cos \theta \sin \phi \\R &= -\dot{\theta} \sin \phi + \dot{\psi} \cos \theta \cos \phi\end{aligned}\tag{A-4}$$

These equations were linearized about two types of trim points for the analysis in this report. These trim conditions were descending flight with wings level and banked flight turns with altitude held constant. Each variable in the equations was expressed as a sum of a trim value and a small perturbation value in the following manner:  $U=U_0+u$ ,  $V=V_0+v$ ,  $W=W_0+w$ ,  $P=P_0+p$ ,  $Q=Q_0+q$ ,  $R=R_0+r$ ,  $\theta=\theta_0+\theta$ ,  $\phi=\phi_0+\phi$ ,  $\psi=\psi_0+\psi$ . These sums were substituted into the equations, all products and trigonometric functions were expanded using identities and power series where necessary, and products and higher powers of the small perturbation variables were neglected. Then, the resulting equations could be separated into a set of non-linear trim equations and a set of linear small perturbation equations, which remain when the trim equation terms were subtracted from the total equations.

The trim equations were identical to the original equations with each variable replaced by the trim value. For example, the first trim moment equation was

$$L_0 = \dot{P}_0 I_{xx} - \dot{R}_0 I_{xz} + Q_0 R_0 (I_{zz} - I_{yy}) - P_0 Q_0 I_{xz}\tag{A-5}$$

Usually the trim equations are further reduced since terms including linear or angular accelerations are zero; e.g.,  $\dot{P}_O = \dot{R}_O = 0$  in Equation (A-5).

The resulting small perturbation force equations were

$$\begin{aligned}\Delta F_x &= m(\dot{u} + W_O q + Q_O w - V_O r - R_O v) \\ \Delta F_y &= m(\dot{v} + U_O r + R_O u - W_O p - P_O w) \\ \Delta F_z &= m(\dot{w} + V_O p + P_O v - U_O q - Q_O u)\end{aligned}\tag{A-6}$$

The resulting small perturbation moment equations were

$$\begin{aligned}\Delta L &= \dot{p}I_{xx} - \dot{r}I_{xz} + Q_O r (I_{zz} - I_{yy}) + [R_O (I_{zz} - I_{yy}) - P_O I_{xz}]q - Q_O I_{xz}p \\ \Delta M &= \dot{q}I_{yy} + [P_O (I_{xx} - I_{zz}) - 2R_O I_{xz}]r + [R_O (I_{xx} - I_{zz}) + 2P_O I_{xz}]p \\ \Delta N &= \dot{r}I_{zz} - \dot{p}I_{xz} + [P_O (I_{yy} - I_{xx}) + R_O I_{xz}]q + [Q_O (I_{yy} - I_{xx}) + Q_O I_{xz}]r\end{aligned}\tag{A-7}$$

The small perturbation Euler Equations were

$$\begin{aligned}p &= \dot{\phi} - (\sin\theta_O)\dot{\psi} - (\dot{\psi}_O \cos\theta_O)\theta \\ q &= (\cos\phi_O)\dot{\theta} + (\cos\theta_O \sin\phi_O)\dot{\psi} - (\dot{\psi}_O \sin\theta_O \sin\phi_O)\theta + \\ &\quad (-\dot{\theta}_O \sin\phi_O + \dot{\psi}_O \cos\theta_O \cos\phi_O)\phi \\ r &= -(\sin\phi_O)\dot{\theta} + (\cos\theta_O \cos\phi_O)\dot{\psi} - (\dot{\psi}_O \sin\theta_O \cos\phi_O)\theta - \\ &\quad (\dot{\theta}_O \cos\phi_O + \dot{\psi}_O \cos\theta_O \sin\phi_O)\phi\end{aligned}\tag{A-8}$$

# Contrails

These equations were then solved readily for the attitude rates

$$\begin{aligned}\dot{\phi} &= p + q \sin \phi_0 \tan \theta_0 + r \cos \phi_0 \tan \theta_0 + (\dot{\psi}_0 / \cos \theta_0) \theta + (\dot{\theta}_0 \tan \theta_0) \phi \\ \dot{\theta} &= q \cos \phi_0 - r \sin \phi_0 - (\dot{\psi}_0 \cos \theta_0) \phi \\ \dot{\psi} &= q \sin \phi_0 / \cos \theta_0 + r \cos \phi_0 / \cos \theta_0 + (\dot{\psi}_0 \tan \theta_0) \theta + (\dot{\theta}_0 / \cos \theta_0) \phi\end{aligned}\tag{A-9}$$

For the specialized trim conditions considered in this analysis (wings level descending or horizontal banked flight) several of the terms were zero, and the equations could be reduced. In addition the axes system chosen for the analysis was the body stability axes which were defined such that the x-stability axis lay along the component of the trim velocity vector in the body x-z plane. Also, the trim sideslip (or side velocity) of the aircraft was assumed zero.

For these conditions the following trim values held:

$P_0 = \dot{\theta}_0 = W_0 = V_0 = 0$ . Dropping the corresponding terms from the equations

$$\Delta F_x = m(\dot{u} + Q_0 w - R_0 v)$$

$$\Delta F_y = m(\dot{v} + U_0 r + R_0 u)$$

$$\Delta F_z = m(\dot{w} - U_0 q - Q_0 u)$$

$$\Delta L = \dot{p} I_{xx} - \dot{r} I_{xz} + Q_0 r (I_{zz} - I_{yy}) + R_0 q (I_{zz} - I_{yy}) - Q_0 p I_{xz}$$

$$\Delta M = \dot{q} I_{yy} - 2R_0 I_{xz} r + R_0 (I_{xx} - I_{zz}) p$$

$$\Delta N = \dot{r} I_{zz} - \dot{p} I_{xz} + R_0 q I_{xz} + Q_0 (I_{yy} - I_{xx} + I_{xz}) r$$

$$\begin{aligned}
 \dot{\phi} &= p + q \sin \phi_0 \tan \theta_0 + r \cos \phi_0 \tan \theta_0 + (\dot{\psi}_0 / \cos \theta_0) \theta \\
 \dot{\theta} &= q \cos \phi_0 - r \sin \phi_0 - (\dot{\psi}_0 \cos \theta_0) \phi \\
 \dot{\psi} &= q \sin \phi_0 / \cos \theta_0 + r \cos \phi_0 / \cos \theta_0 + (\dot{\psi}_0 \tan \theta_0) \theta
 \end{aligned}
 \tag{A-10}$$

For horizontal banked flight  $\theta_0 = 0$ . Then from Equations (A-4) substitution of the trim values yielded

$$\begin{aligned}
 Q_0 &= \dot{\psi}_0 \sin \phi_0 \\
 R_0 &= \dot{\psi}_0 \cos \phi_0
 \end{aligned}
 \tag{A-11}$$

These expressions could be substituted into the force and moment equations to eliminate  $Q_0$  and  $R_0$  and to introduce the bank angle  $\phi_0$  and turn rate  $\dot{\psi}_0$  into each equation. However, no further terms were eliminated by this step, except in the Euler Equations which became

$$\begin{aligned}
 \dot{\phi} &= p + \dot{\psi}_0 \theta \\
 \dot{\theta} &= q \cos \phi_0 - r \sin \phi_0 - \dot{\psi}_0 \phi \\
 \dot{\psi} &= q \sin \phi_0 + r \cos \phi_0
 \end{aligned}
 \tag{A-12}$$

Further simplifications also resulted for wings level descending flight were  $Q_0 = R_0 = \dot{\psi}_0 = \phi_0 = 0$ . After introduction of these values the equations became

$$\begin{aligned}
 \Delta F_x &= m \dot{u} \\
 \Delta F_y &= m(\dot{v} + U_0 r)
 \end{aligned}$$

# Contrails

$$\begin{aligned}\Delta F_z &= m(\dot{w} - U_0 q) \\ \Delta L &= \dot{p}I_{xx} - \dot{r}I_{xz} \\ \Delta M &= \dot{q}I_{yy} \\ \Delta N &= \dot{r}I_{zz} - \dot{p}I_{xz} \\ \dot{\phi} &= p + r \tan \theta_0 \\ \dot{\theta} &= q \\ \dot{\psi} &= r(1/\cos \theta_0)\end{aligned}\tag{A-13}$$

Certain remarks about these equations are appropriate at this point. The banked flight equations are "inertially coupled" such that the first eight equations involving the eight variables  $u, w, v, p, q, r, \theta,$  and  $\phi$  must be solved simultaneously. The ninth equation yields the yaw angle  $\psi$  in terms of these other eight variables. However, for the level flight case these eight equations can be inertially decoupled into two sets of four equations: the longitudinal mode involving the force equations for  $F_x, F_z,$  the moment equation for  $M,$  and the  $\theta$  Euler-equation in terms of the variables  $u, w, q,$  and  $\theta;$  and the lateral-directional mode involving the remaining equations  $F_y, L, N,$  and  $\phi$  in terms of the variables  $v, p, r,$  and  $\phi.$  This decoupling holds as long as there is no "aerodynamic" cross coupling of the forces and moments, which are discussed in the next section.

## Forces and Moments:

The forces and moments consist of the gravitational force and the propulsion and aerodynamic forces and moments.

# Contrails

The gravitational force is of course directed downwards, and its components in the body stability axes are obtained by transforming through the Euler angles. The resulting equations are

$$\begin{aligned}F_{g_x} &= -mg \sin \theta \\F_{g_y} &= mg \cos \theta \sin \phi \\F_{g_z} &= mg \cos \theta \cos \phi\end{aligned}\tag{A-14}$$

The linearized small perturbation gravity forces are then

$$\begin{aligned}\Delta F_{g_x} &= -mg (\cos \theta_0) \theta \\ \Delta F_{g_y} &= mg [(\cos \theta_0 \cos \phi_0) \phi - (\sin \theta_0 \sin \phi_0) \theta] \\ \Delta F_{g_z} &= -mg [(\cos \theta_0 \sin \phi_0) \phi + (\sin \theta_0 \cos \phi_0) \theta]\end{aligned}\tag{A-15}$$

For "wings level" ( $\phi_0=0$ ) these become

$$\begin{aligned}\Delta F_{g_x} &= -mg (\cos \theta_0) \theta \\ \Delta F_{g_y} &= mg (\cos \theta_0) \phi \\ \Delta F_{g_z} &= -mg (\sin \theta_0) \theta\end{aligned}\tag{A-16}$$

For "banked flight" ( $\theta_0=0$ ) they become

$$\begin{aligned}
 \Delta F_{g_x} &= -mg\theta \\
 \Delta F_{g_y} &= mg(\cos\phi_0)\phi \\
 \Delta F_{g_z} &= -mg(\sin\phi_0)\phi
 \end{aligned}
 \tag{A-17}$$

To obtain linearized expressions for the aerodynamic and propulsion forces these total forces were expanded in Taylor series as a function of the eight variables in the coupled equations and derivatives of these variables. In addition, the aircraft aerodynamic control surface deflections, the elevator,  $\delta_e$ , aileron,  $\delta_a$ , rudder,  $\delta_r$ , and the engine throttle control,  $\delta_T$ , were included as variables. For example, the expansion of the x-axis aerodynamic-propulsion force,  $F_{x_A}$ , is

$$\begin{aligned}
 F_{x_A} &= F_{x_{A_0}} + \frac{\partial F_{x_A}}{\partial u} u + \frac{\partial F_{x_A}}{\partial v} v + \frac{\partial F_{x_A}}{\partial w} w + \frac{\partial F_{x_A}}{\partial p} p + \\
 &\frac{\partial F_{x_A}}{\partial q} q + \frac{\partial F_{x_A}}{\partial r} r + \frac{\partial F_{x_A}}{\partial \delta_e} \delta_e + \frac{\partial F_{x_A}}{\partial \delta_a} \delta_a + \\
 &\frac{\partial F_{x_A}}{\partial \delta_r} \delta_r + \frac{\partial F_{x_A}}{\partial \delta_T} \delta_T + \frac{\partial F_{x_A}}{\partial \dot{u}} \dot{u} + \frac{\partial F_{x_A}}{\partial \dot{v}} \dot{v} + \\
 &\frac{\partial F_{x_A}}{\partial \dot{w}} \dot{w} + \frac{\partial F_{x_A}}{\partial \dot{p}} \dot{p} + \dots
 \end{aligned}
 \tag{A-18}$$

# Contrails

In this form each of the partial derivatives shown in this expansion is actually a derivative with respect to the "total" variable, not the perturbation variable, and is to be evaluated at the trim conditions. For example

$$\frac{\partial F_{x_A}}{\partial u} \equiv \frac{\partial F_{x_A}}{\partial U} \Big|_{(U_0, V_0, W_0, P_0, Q_0, R_0, \theta_0, \phi_0, \delta_{e_0}, \delta_{a_0}, \delta_{r_0}, \delta_{T_0})} \quad (\text{A-19})$$

In actual practice many of the derivatives are zero, and the remainder are generally presented in a form which is non-dimensionalized by multiplication and division by appropriate parameters. The linear small perturbation velocities are also non-dimensionalized in each of the force equations by dividing by the trim velocity

$$\begin{aligned} \underline{u} &= u/U_0 \\ \alpha &= w/U_0 \\ \beta &= v/U_0 \end{aligned} \quad (\text{A-20})$$

The second two non-dimensional variables,  $\alpha$  and  $\beta$ , are the perturbation angle-of-attack and the perturbation sideslip angle, respectively.

To convert the equations of motion for introduction of the non-dimensional stability derivatives the force equations are divided by the factor  $(Sq_0)$ , which is the product of reference wing area and dynamic pressure; the L-moment and N-moment equations are divided by  $(Sq_0 b)$ , where  $b$  is the wing span; the M-moment equation is divided by  $(Sq_0 c)$ , where  $c$  is

# Contrails

the mean aerodynamic chord. In addition, other factors are introduced within some of the derivative expressions. The resulting perturbation aerodynamic and propulsion force and moment equations are as follows. (Only significant derivatives are retained. No confusion should result from dropping the subscript zero from  $U_0$  and  $q_0$ .)

$$\begin{aligned} \left(\frac{1}{Sq}\right) \Delta F_{x_A} &= \left(\frac{U}{Sq} \frac{\partial F_x}{\partial u}\right) \underline{u} + \left(\frac{U}{Sq} \frac{\partial F_x}{\partial w}\right) \alpha + \left(\frac{1}{Sq} \frac{\partial F_x}{\partial \delta_T}\right) \delta_T \\ &= C_{x_u} \underline{u} + C_{x_\alpha} \alpha + C_{x_{\delta_T}} \delta_T \end{aligned}$$

$$\begin{aligned} \left(\frac{1}{Sq}\right) \Delta F_{y_A} &= \left(\frac{U}{Sq} \frac{\partial F_y}{\partial v}\right) \beta + \left(\frac{1}{Sq} \frac{\partial F_y}{\partial \delta_a}\right) \delta_a + \left(\frac{1}{Sq} \frac{\partial F_y}{\partial \delta_r}\right) \delta_r \\ &= C_{y_\beta} \beta + C_{y_{\delta_a}} \delta_a + C_{y_{\delta_r}} \delta_r \end{aligned}$$

$$\begin{aligned} \left(\frac{1}{Sq}\right) \Delta F_{z_A} &= \left(\frac{U}{Sq} \frac{\partial F_z}{\partial u}\right) \underline{u} + \left(\frac{U}{Sq} \frac{\partial F_z}{\partial w}\right) \alpha + \left(\frac{1}{Sq} \frac{2U}{c} \frac{\partial F_z}{\partial q}\right) \frac{c}{2U} q + \\ &\quad \left(\frac{U}{Sq} \frac{2U}{c} \frac{\partial F_z}{\partial \dot{w}}\right) \frac{c}{2U} \dot{\alpha} + \left(\frac{1}{Sq} \frac{\partial F_z}{\partial \delta_e}\right) \delta_e + \left(\frac{1}{Sq} \frac{\partial F_z}{\partial \delta_T}\right) \delta_T \\ &= C_{z_u} \underline{u} + C_{z_\alpha} \alpha + \frac{c}{2U} C_{z_q} q + \frac{c}{2U} C_{z_{\dot{\alpha}}} \dot{\alpha} + \\ &\quad C_{z_{\delta_e}} \delta_e + C_{z_{\delta_T}} \delta_T \end{aligned}$$

$$\begin{aligned} \left(\frac{1}{Sq b}\right) \Delta L &= \left(\frac{U}{Sq b} \frac{\partial L}{\partial v}\right) \beta + \left(\frac{1}{Sq b} \frac{2U}{b} \frac{\partial L}{\partial p}\right) \left(\frac{b}{2U}\right) p + \left(\frac{1}{Sq b} \frac{2U}{b} \frac{\partial L}{\partial r}\right) \left(\frac{b}{2U}\right) r + \\ &\quad \left(\frac{1}{Sq b} \frac{\partial L}{\partial \delta_a}\right) \delta_a + \left(\frac{1}{Sq b} \frac{\partial L}{\partial \delta_r}\right) \delta_r \\ &= C_{l_\beta} \beta + \left(\frac{b}{2U}\right) C_{l_p} p + \left(\frac{b}{2U}\right) C_{l_r} r + C_{l_{\delta_a}} \delta_a + C_{l_{\delta_r}} \delta_r \end{aligned}$$

# Contrails

$$\begin{aligned}
 \left(\frac{1}{Sqc}\right) \Delta M &= \left(\frac{U}{Sqc} \frac{\partial M}{\partial u}\right) \underline{u} + \left(\frac{U}{Sqc} \frac{\partial M}{\partial w}\right) \alpha + \left(\frac{U}{Sqc} \frac{2U}{c} \frac{\partial M}{\partial \dot{w}}\right) \left(\frac{c}{2U}\right) \dot{\alpha} + \\
 &\quad \left(\frac{1}{Sqc} \frac{2U}{c} \frac{\partial M}{\partial q}\right) \left(\frac{c}{2U}\right) q + \left(\frac{1}{Sqc} \frac{\partial M}{\partial \delta_e}\right) \delta_e + \left(\frac{1}{Sqc} \frac{\partial M}{\partial \delta_T}\right) \delta_T \\
 &= C_{m_u} \underline{u} + C_{m_\alpha} \alpha + \left(\frac{c}{2U}\right) C_{m_\alpha} \dot{\alpha} + \left(\frac{c}{2U}\right) C_{m_q} q + C_{m_{\delta_e}} \delta_e + \\
 &\quad C_{m_{\delta_T}} \delta_T \\
 \left(\frac{1}{Sq_b}\right) \Delta N &= \left(\frac{U}{Sq_b} \frac{\partial N}{\partial v}\right) \beta + \left(\frac{1}{Sq_b} \frac{2U}{b} \frac{\partial N}{\partial p}\right) \left(\frac{b}{2U}\right) p + \left(\frac{1}{Sq_b} \frac{2U}{b} \frac{\partial N}{\partial r}\right) \left(\frac{b}{2U}\right) r + \\
 &\quad \left(\frac{1}{Sq_b} \frac{\partial N}{\partial \delta_a}\right) \delta_a + \left(\frac{1}{Sq_b} \frac{\partial N}{\partial \delta_r}\right) \delta_r \\
 &= C_{n_\beta} \beta + \left(\frac{b}{2U}\right) C_{n_p} p + \left(\frac{b}{2U}\right) C_{n_r} r + C_{n_{\delta_a}} \delta_a + C_{n_{\delta_r}} \delta_r
 \end{aligned}$$

(A-21)

The NACA standard non-dimensional stability derivatives were substituted following the definitions presented in Blakelock<sup>22</sup>. One of the derivatives was calculated using the following relation from Reference 22.

$$C_{z_{\delta_e}} = \frac{c}{l_t} C_{m_{\delta_e}} \tag{A-22}$$

where  $l_t$  is the distance from the aircraft center of gravity to the aerodynamic center of the horizontal tail.

At this point we should note that the linear and angular velocities in the acceleration terms of Equations (A-1) through (A-13) are by definition "inertial" or ground reference velocities in agreement with Newton's laws of motion. In contrast, the corresponding velocities in the force

equations are by definition "airspeeds" since the aerodynamic and propulsion forces are generated by motion of the propellers and aerodynamic surfaces with respect to the air mass. Consistency is achieved in the equations by shifting the inertial reference frame from the ground to the air mass. The accelerations are not changed by this step since the air mass is not rotating, and the air is assumed to have constant velocity at a given altitude. The extra steady acceleration of the air mass produced by vertical wind gradients appears in the trim equations and thus does not alter the small perturbation equations for descending flight.

#### Atmospheric Turbulence:

The "gust model" used in this analysis is based on the Dryden model described in References 18 and 26. A more detailed description of this model is presented in the section, Gust State Equations. The equations that are appropriate for this section are those that relate the aircraft air reference velocities and the gust velocities. Since the ground reference velocity is the sum of the velocity with respect to the air plus the velocity of the air relative to ground we have the following expressions

$$\begin{aligned} \underline{u} &= \underline{u}_a + \underline{u}_g & p &= p_a + p_g \\ \alpha &= \alpha_a + \alpha_g & q &= q_a + q_g \\ \beta &= \beta_a + \beta_g & r &= r_a + r_g \end{aligned} \tag{A-23}$$

# Contrails

where the subscript "a" denotes air relative velocities and "g" denotes the gust velocities. It should be stated that the positive sense of the gust velocities is not critical since the gusts are assumed to be zero mean, Gaussian, random variables. The next logical step would be to solve for each air speed and substitute the resulting expression for each corresponding speed in the aircraft equations. For example:  $\underline{u}_a = \underline{u} - \underline{u}_g$ , where  $\underline{u}_a$  is equivalent to  $\underline{u}$  in the aircraft equations. This step was accomplished, but in keeping with the gust model of Reference 18 the gusts were assumed to enter the equations only through the aerodynamic forces. Thus, substitutions were made only for the velocities in the force Equations (A-21). This substitution introduced another apparent inconsistency: air relative velocities in the acceleration terms contrasted with ground relative velocities in the force terms. However, we note that for a steady wind velocity the ground relative perturbation velocities are also air reference perturbation velocities. Therefore, there is no inconsistency if we consider all perturbation velocities to be air relative or airspeeds. When the substitutions are made and the acceleration, gravitational, and aerodynamic and propulsion force equations are combined (Equations (A-10), (A-15), (A-21), and (A-23)), we obtain the following equations, where only the rate terms are placed on the lefthand side. (Again the subscript zero is dropped from  $U_0$  and  $q_0$ .)

# Contrails

$$\frac{mU}{Sq} \dot{u} = - \frac{mUQ_o}{Sq} \alpha + \frac{mUR_o}{Sq} \beta - \frac{mg \cos \theta_o}{Sq} \theta + C_{x_u} \underline{u} + C_{x_\alpha} \alpha +$$

$$C_{x_{\delta_T}} \delta_T - C_{x_u} \underline{u}_g - C_{x_\alpha} \alpha_g$$

$$\frac{mU}{Sq} \dot{\beta} = - \frac{mU}{Sq} r - \frac{mUR_o}{Sq} \underline{u} + \left( \frac{mg}{Sq} \cos \theta_o \cos \phi_o \right) \phi - \left( \frac{mg}{Sq} \sin \theta_o \sin \phi_o \right) \theta +$$

$$C_{Y_\beta} \beta + C_{Y_{\delta_a}} \delta_a + C_{Y_{\delta_r}} \delta_r - C_{Y_\beta} \beta_g$$

$$\left( \frac{mg}{Sq} \sin \theta_o \cos \phi_o \right) \theta + C_{z_u} \underline{u} + C_{z_\alpha} \alpha + \frac{C}{2U} C_{z_q} q +$$

$$C_{z_{\delta_e}} \delta_e + C_{z_{\delta_T}} \delta_T - \frac{C}{2U} C_{z_\alpha} \dot{\alpha}_g - C_{z_u} \underline{u}_g -$$

$$C_{z_\alpha} \alpha_g - \frac{C}{2U} C_{z_q} q_g$$

$$\frac{I_{xx}}{Sq b^2} \dot{p} - \frac{I_{xz}}{Sq b} \dot{r} = \frac{-Q_o (I_{zz} - I_{yy})}{Sq b} r - \frac{R_o (I_{zz} - I_{yy})}{Sq b} q + \frac{Q_o I_{xz}}{Sq b} p +$$

$$C_{l_\beta} \beta + \left( \frac{b}{2U} \right) C_{l_p} p + \left( \frac{b}{2U} \right) C_{l_r} r + C_{l_{\delta_a}} \delta_a +$$

$$C_{l_{\delta_r}} \delta_r - C_{l_\beta} \beta_g - \left( \frac{b}{2U} \right) C_{l_p} p_g - \left( \frac{b}{2U} \right) C_{l_r} r_g$$

$$\frac{I_{yy}}{Sq c} \dot{q} - \left( \frac{C}{2U} \right) C_{m_\alpha} \dot{\alpha} = \frac{2R_o I_{xz}}{Sq c} r - \frac{R_o (I_{xx} - I_{zz})}{Sq c} p + C_{m_u} \underline{u} +$$

$$C_{m_\alpha} \alpha + \left( \frac{C}{2U} \right) C_{m_q} q + C_{m_{\delta_e}} \delta_e + C_{m_{\delta_T}} \delta_T -$$

$$C_{m_u} \underline{u}_g - \left( \frac{C}{2U} \right) C_{m_\alpha} \dot{\alpha}_g - C_{m_\alpha} \alpha_g - \left( \frac{C}{2U} \right) C_{m_q} q_g$$

# Contrails

$$\begin{aligned} \frac{I_{zz} \dot{r}}{Sqb} - \frac{I_{xz} \dot{p}}{Sqb} = & - \frac{R_0 I_{xz}}{Sqb} q - \frac{Q_0 (I_{yy} - I_{xx} + I_{xz})}{Sqb} r + C_{n_\beta} \beta + \\ & \left(\frac{b}{2U}\right) C_{n_p} p + \left(\frac{b}{2U}\right) C_{n_r} r + C_{n_{\delta_a}} \delta_a + C_{n_{\delta_r}} \delta_r - \\ & C_{n_\beta} \beta_g - \left(\frac{b}{2U}\right) C_{n_p} p_g - \left(\frac{b}{2U}\right) C_{n_r} r_g \end{aligned} \quad (A-24)$$

In the Dryden model only the four gust velocities  $\underline{u}_g$ ,  $\alpha_g$ ,  $\beta_g$ , and  $p_g$  are defined to be mutually statistically independent. It is then desirable to eliminate the two other velocities,  $q_g$  and  $r_g$ . This is readily done since it can be shown that  $q_g = \partial w_g / \partial x = -\dot{\alpha}_g$  and  $r_g = -\partial v_g / \partial x = \dot{\beta}_g$ , using the sign conventions of Reference 18. However, care must be exercised in the use of these angular gust velocities. Note that  $r_g$  represents the spatial variation of the side gust velocity along the longitudinal x-body axis. As explained in Reference 26, the rolling moment due to yawing velocity actually results from "spanwise" variation in the "forward" airspeed due to yawing velocity. Thus, the term containing  $(C_{l_r} r_g)$  should be dropped from the L-moment of Equations (A-24). When the substitutions are made the following changes in terms result. In the z-force  $\dot{\alpha}$  equation

$$- \left(\frac{C}{2U}\right) C_{z_q} q_g - \left(\frac{C}{2U}\right) C_{z_\alpha} \dot{\alpha}_g = \left(\frac{C}{2U}\right) (C_{z_q} - C_{z_\alpha}) \dot{\alpha}_g \quad (A-25)$$

In the M-moment equation

$$- \left(\frac{C}{2U}\right) C_{m_\alpha} \dot{\alpha}_g - \left(\frac{C}{2U}\right) C_{m_q} q_g = \left(\frac{C}{2U}\right) (C_{m_q} - C_{m_\alpha}) \dot{\alpha}_g \quad (A-26)$$

In the N-moment equation

$$- \left(\frac{b}{2U}\right) C_{n_r} r_g = - \left(\frac{b}{2U}\right) C_{n_r} \dot{\beta}_g \quad (\text{A-27})$$

**Aircraft Equations in State-Vector Form:**

The development of the aircraft equations has been directed toward their expression in the following state-vector form

$$\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u} + \mathbf{G}\eta \quad (\text{A-28})$$

where  $\mathbf{x}$  is the aircraft state vector,  $\mathbf{u}$  is the control vector,  $\eta$  is the vector of stochastic disturbance inputs, and  $\mathbf{A}$ ,  $\mathbf{B}$ , and  $\mathbf{G}$  are the corresponding matrices of constant coefficients. To get the aircraft equations into this form we eliminate all but one state-derivative term from each equation and divide by the coefficients of that remaining rate term. When this is done we obtain the equations in the following form (where only terms that are non-zero for either  $\theta_o=0$  or  $\phi_o=0$  have been retained, common parameters have been grouped, and the equations have been reordered

$$\begin{aligned} \dot{\underline{u}} = & f_1 C_{x_u} \underline{u} + (f_1 C_{x_\alpha} - Q_o) \alpha - \left(\frac{g}{U} \cos \theta_o\right) \theta + R_o \beta + f_1 C_{x_{\delta_T}} \delta_T - \\ & f_1 C_{x_u} \underline{u}_g - f_1 C_{x_\alpha} \alpha_g \\ \dot{\underline{\alpha}} = & f_3 (f_1 C_{z_u} + Q_o) \underline{u} + (f_1 f_3 C_{z_\alpha}) \alpha + f_3 (1 + f_2 C_{z_q}) q - \\ & (f_3 \frac{g}{3U} \sin \theta_o) \theta - (f_3 \frac{g}{3U} \sin \phi_o) \phi + (f_1 f_3 \frac{C}{l_t} C_{m_{\delta_e}}) \delta_e + \end{aligned}$$

# Controls

$$+ (f_1 f_3 C_{z_{\delta_T}}) \delta_T - (f_1 f_3 C_{z_u}) \underline{u}_g - (f_1 f_3 C_{z_\alpha}) \alpha_g +$$

$$(C_{n_{r_g}}) \dot{\beta}_g - (f_7 C_{n_p}') p_g$$

# Contrails

$$\begin{aligned} \dot{\beta} &= - (R_O) \underline{u} - r + (f_1 C_{Y_\beta}) \beta + \left( \frac{g}{U} \cos \phi_O \cos \theta_O \right) \phi + (f_1 C_{Y_{\delta_a}}) \delta_a + \\ &\quad (f_1 C_{Y_{\delta_r}}) \delta_r - (f_1 C_{Y_\beta}) \beta g \\ \dot{\phi} &= (\dot{\psi}_O) \theta + p + (\tan \theta_O) r \\ \dot{\psi} &= (\sin \phi_O) q + (\cos \phi_O / \cos \theta_O) r \end{aligned} \tag{A-29}$$

where

$$\begin{aligned} f_1 &= Sq / (mU) \\ f_2 &= f_1 f_8 \\ f_3 &= 1 / (1 - f_2 C_{z'_a}) \\ f_4 &= f_8 f_y \\ f_5 &= 1 / (1 - f_9) \\ f_6 &= f_x b / (2U) \\ f_7 &= f_z b / (2U) \\ f_8 &= c / (2U) \\ f_9 &= I_{xz}^2 / (I_{xx} I_{zz}) \\ f_{10} &= (I_{yy} - I_{xx}) / I_{zz} \\ f_{11} &= (I_{zz} - I_{yy}) / I_{xx} \\ f_{12} &= f_5 (f_9 + f_{11}) \\ f_{13} &= f_5 (1 + f_{11}) I_{xz} / I_{zz} \end{aligned}$$

$$\begin{aligned}f_x &= Sq_b/I_{xx} \\f_y &= Sq_c/I_{yy} \\f_z &= Sq_b/I_{zz}\end{aligned}\tag{A-30}$$

and where the primed stability derivatives are the standard derivatives in the literature which result from the simultaneous solution of the L-moment and N-moment equations to eliminate the  $\dot{r}$  and  $\dot{p}$  terms, respectively. This elimination involves multiplication by the appropriate moment or product of inertia and addition of the equations. Each primed derivative is identical in form to the following expressions, where the subscript (i) is used to represent  $\beta$ ,  $p$ ,  $r$ ,  $\delta_a$ , or  $\delta_r$ . For the L-moment equation derivatives

$$C_{l_i}' = f_5 \left( C_{l_i} + \frac{I_{xz}}{I_{zz}} C_{n_i} \right)\tag{A-31}$$

For the N-moment equation derivatives

$$C_{n_i}' = f_5 \left( C_{n_i} + \frac{I_{xz}}{I_{xx}} C_{l_i} \right)\tag{A-32}$$

The two special gust derivatives remaining after dropping the term  $(C_{l_r} r_g)$  are

$$C_{l_{r_g}} = f_5 f_6 \frac{I_{xz}}{I_{zz}} C_{n_r}$$
$$C_{n_{r_g}} = f_5 f_7 C_{n_r}$$

(A-33)

It should be emphasized that these equations hold only for the two special trim conditions of (1) wings level descending or (2) horizontal banked flight. For example, in the  $\dot{\psi}$ -equation, Equations (A-29), the denominator factor  $(\cos \theta_0)$  has been omitted from the coefficient of  $q$  as can be seen by referencing Equations (A-10). The entire  $\theta$ -coefficient  $(\dot{\psi}_0 \tan \theta_0)$  has also been omitted. But Equations (A-29) still reduce to the correct equations for the two chosen trim conditions where either  $\theta_0=0$  or  $\phi_0=0$ .

### Servo Actuator Equations

Each of the four controls for the aircraft was assumed to be driven by or to respond in a mode associated with a servo actuator with a first order lag. The actuator break frequency for the elevator, aileron, and rudder servos was chosen to be 10 radians/sec while the break frequency for the more sluggish throttle was taken to be 1 rad/sec. The actuator state equations were as follows

$$\begin{aligned}\dot{\delta}_e &= - (10) \delta_e + (10) \delta_{e_c} \\ \dot{\delta}_a &= - (10) \delta_a + (10) \delta_{a_c} \\ \dot{\delta}_r &= - (10) \delta_r + (10) \delta_{r_c} \\ \dot{\delta}_T &= - \delta_T + \delta_{T_c}\end{aligned}\tag{A-34}$$

where the subscript c indicates the command input to the actuator.

### Flight Path Displacement Equations

For this analysis the aircraft was assumed to have a microwave landing system signal and adequate onboard instrumentation and computational equipment to determine (without additional error) the aircraft heading and flight path deviation. The reference flight path was assumed to be available to the aircraft via the information channel of the microwave system or by other means, and the aircraft was assumed to be trimmed at a reference point on this flight path. Under these assumptions we can develop the small perturbation linear equations for the flight path errors. The small perturbation attitude equations have already been presented in Equations (A-29). The ground reference velocities are the sum of the airspeeds and the air motion or wind speed. Since the wind is steady it appears only in the trim equations. Development of the displacement equations then requires transforming the body-axes perturbation velocities  $u$ ,  $v$ , and

w into the appropriate path-error coordinate system.

In order to calculate these path errors in a form in which they can be presented to the pilot in a logical manner for the banked flight case we chose the path-error coordinates to be aligned such that their y-z-plane is orthogonal to the trimmed flight path with the y-axis coincident with the trimmed body y-axis and the z-axis "upward" or opposite to the body z-axis. For a righthanded system this requires the x-axis to be opposite to the forward velocity.

The transformation from body rates back through the Euler angles to the rates in the horizontal earth reference axes is represented by the vector-matrix equation

$$\dot{\mathbf{x}}_e = \begin{bmatrix} \cos\psi\cos\theta & [-\cos\phi\sin\psi + \sin\phi\cos\psi\sin\theta] & (\sin\phi\sin\psi + \cos\phi\cos\psi\sin\theta) \\ \cos\theta\sin\psi & [\cos\psi\cos\phi + \sin\phi\sin\psi\sin\theta] & (-\cos\psi\sin\phi + \cos\phi\sin\psi\sin\theta) \\ -\sin\theta & \cos\theta\sin\phi & \cos\theta\cos\phi \end{bmatrix} \dot{\mathbf{x}}_b \quad (\text{A-35})$$

where  $\dot{\mathbf{x}}_b = [U_0 + u, v, w]$ .

When the terms in the matrix are linearized for wings level flight where  $\phi_0 = 0$  and  $\psi_0 = 0$ , Equation (A-35) becomes

$$\dot{\mathbf{x}}_e = \begin{bmatrix} \cos\theta_0 - \theta\sin\theta_0 & (-\psi + \phi\sin\theta_0) & (\sin\theta_0 + \theta\cos\theta_0) \\ \psi\cos\theta_0 & 1 & -\phi + \psi\sin\theta_0 \\ -(\sin\theta_0 + \theta\cos\theta_0) & \phi\cos\theta_0 & (\cos\theta_0 - \theta\sin\theta_0) \end{bmatrix} \dot{\mathbf{x}}_b \quad (\text{A-36a})$$

And for horizontal banked flight, where  $\theta_0 = \psi_0 = 0$

$$\dot{\mathbf{x}}_e = \begin{bmatrix} 1 & (\psi \cos \phi_0 + \theta \sin \phi_0) & (\psi \sin \phi_0 + \theta \cos \phi_0) \\ \psi & (\cos \phi_0 - \phi \sin \phi_0) & (-\sin \phi_0 - \phi \cos \phi_0) \\ -\theta & (\sin \phi_0 + \phi \cos \phi_0) & (\cos \phi_0 - \phi \sin \phi_0) \end{bmatrix} \dot{\mathbf{x}}_b \quad (\text{A-36b})$$

Performing the matrix multiplication, further linearizing by neglecting products of small perturbation variables, and subtracting the constant trim terms we obtain the level flight equations (again dropping the zero subscript on  $U_0$ )

$$\begin{aligned} u_e &= (U \cos \theta_0) \underline{u} + (U \sin \theta_0) \alpha - (U \sin \theta_0) \theta \\ v_e &= U \beta + (U \cos \theta_0) \psi \\ w_e &= -(U \sin \theta_0) \underline{u} + (U \cos \theta_0) \alpha - (U \cos \theta_0) \theta \end{aligned} \quad (\text{A-37a})$$

And for banked flight

$$\begin{aligned} u_e &= U \underline{u} \\ v_e &= -(U \sin \phi_0) \alpha + (U \cos \phi_0) \beta + U \psi \\ w_e &= (U \cos \phi_0) \alpha - U \theta + (U \sin \phi_0) \beta \end{aligned} \quad (\text{A-37b})$$

These velocities can then be transformed to the respective glideslopes. For the descending flight case they are rotated downward through the glideslope angle  $\Gamma_0 = -\theta_0$ , the negative of the trim climb angle,

# Contrails

$$\begin{bmatrix} u_{gs} \\ v_{gs} \\ w_{gs} \end{bmatrix} = \begin{bmatrix} \cos\theta_o & 0 & -\sin\theta_o \\ 0 & 1 & 0 \\ \sin\theta_o & 0 & \cos\theta_o \end{bmatrix} \begin{bmatrix} u_e \\ v_e \\ w_e \end{bmatrix} \quad (\text{A-38a})$$

And for the banked flight case they are banked through the angle  $\phi_o$ , the trim bank angle,

$$\begin{bmatrix} u_{gs} \\ v_{gs} \\ w_{gs} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi_o & \sin\phi_o \\ 0 & -\sin\phi_o & \cos\phi_o \end{bmatrix} \begin{bmatrix} u_e \\ v_e \\ w_e \end{bmatrix} \quad (\text{A-38b})$$

Performing the matrix multiplications we obtain the wings-level descending equations

$$\begin{aligned} u_{gs} &= U\underline{u} \\ v_{gs} &= U\underline{\beta} + (U\cos\theta_o)\psi \\ w_{gs} &= U\underline{\alpha} - U\underline{\theta} \end{aligned} \quad (\text{A-39a})$$

And for banked flight

$$\begin{aligned} u_{gs} &= U\underline{u} \\ v_{gs} &= - (U\sin\phi_o)\underline{\theta} + U\underline{\beta} + (U\cos\phi_o)\psi \\ w_{gs} &= U\underline{\alpha} - (U\cos\phi_o)\underline{\theta} - (U\sin\phi_o)\psi \end{aligned} \quad (\text{A-39b})$$

# Contrails

For this analysis we combined these into one set of equations in such a manner that the combined set reduced to the two special cases. The resulting equations were

$$\begin{aligned}u_{gs} &= U\underline{u} \\v_{gs} &= - (U\sin\phi_o)\theta + U\beta + (U\cos\theta_o\cos\phi_o)\psi \\w_{gs} &= U\alpha - (U\cos\phi_o)\theta - (U\sin\phi_o)\psi\end{aligned}\tag{A-40}$$

Note that the combined set does not necessarily hold for any case in which both  $\theta_o$  and  $\phi_o$  are non-zero simultaneously.

Finally, recalling the definition of the path-error coordinates, we obtain the flight path displacement equations

$$\begin{aligned}\dot{d}_x &= -u_{gs} = -U\underline{u} \\ \dot{d}_y &= v_{gs} = - (U\sin\phi_o)\theta + U\beta + (U\cos\theta_o\cos\phi_o)\psi \\ \dot{d}_z &= -w_{gs} = -U\alpha + (U\cos\phi_o)\theta + (U\sin\phi_o)\psi\end{aligned}\tag{A-41}$$

where only the equations for  $\dot{d}_y$  and  $\dot{d}_z$  were used in this analysis.

## Gust State-Vector Equations

The stochastic model of the atmospheric turbulence ("gust model") used in this analysis is based upon the model in Reference 18. In order to facilitate linear analysis this gust model was assumed to be an ergodic, Gaussian, zero mean random process that is horizontally isotropic. These

# Contrails

assumptions allow the model to be represented in the form of gust power spectral densities for three linear gust velocities and three angular gust velocities along axes coincident with the aircraft body axes. The three linear gust velocities and the rolling angular gust velocity are assumed to be mutually statistically independent random processes. The power spectra used in this analysis were the Dryden form, which consist of ratios of rational polynomials. These spectra were derived empirically from actual gust data.

We will elaborate on these assumptions briefly. The fact that the model is ergodic derives from Taylor's hypothesis that the gust field is stationary in time and homogeneous in space in such a manner that a time history of the process at a point in the air has the same statistical properties as those throughout the spatial dimensions. For example, gust measurements at a tower near an airport are representative of the gusts encountered by an aircraft flying in the vicinity. Horizontal isotropy insures that the longitudinal and side gust velocities acting on an aircraft in horizontal flight are independent of the aircraft heading, and it insures that the rms intensities of these two gusts are equal. Above a certain altitude isotropy is extended to all three directions. However, near the ground the rms intensity of the vertical gust is reduced in relation to the horizontal intensities. This anisotropy is significant for landing problems. The assumption that the process is

# Contrails

Gaussian allows complete description of the process with its second order statistics, the power spectral densities. In addition, it allows use of the following input-output relation from Reference 28

$$\phi_o(\omega) = |T(j\omega)|^2 \phi_i(\omega) \quad (\text{A-42})$$

where  $\phi_i(\omega)$  and  $\phi_o(\omega)$  are the input and output power spectra and  $T(s)$  is the system transfer function. The assumption that the process along each aircraft axis is statistically independent simplifies the mathematics in that the cross-spectra for the process are zero. However, non-zero cross-spectra can still be handled in a linear analysis, especially the state vector formulation employed in this study.

The Dryden power spectra for the four independent gust velocities are given in Reference 18 as follows

$$\begin{aligned} \phi_u(\Omega) &= \sigma_u^2 \frac{2L_u}{\pi} \frac{1}{1+(L_u\Omega)^2} \\ \phi_v(\Omega) &= \sigma_v^2 \frac{L_v}{\pi} \frac{1+3(L_v\Omega)^2}{[1+(L_v\Omega)^2]^2} \\ \phi_w(\Omega) &= \sigma_w^2 \frac{L_w}{\pi} \frac{1+3(L_w\Omega)^2}{[1+(L_w\Omega)^2]^2} \\ \phi_p(\Omega) &= \frac{\sigma_w^2}{L_w} \frac{0.8[\pi L_w/(4b)]^{1/3}}{1+(4b/\pi\Omega)^2} \end{aligned} \quad (\text{A-43})$$

where  $\Omega = \omega / U_0$  is the spatial frequency,  $\omega$  is the temporal frequency,  $\sigma_u$ ,  $\sigma_v$ , and  $\sigma_w$  are the rms gust intensities, and  $L_u$ ,  $L_v$ , and  $L_w$  are the gust scale lengths. The vertical intensity,  $\sigma_w$ , is a function of altitude and the "level" of turbulence. For severe turbulence it is given by a plot in Reference 18, where it is a maximum of about 6.5 ft/sec near an altitude of 100 ft. The scale lengths are given as follows

$$\begin{aligned} \text{For } h \geq 1750 \text{ (ft)} \\ L_u = L_v = L_w = 1750 \\ \text{For } h < 1750 \text{ (ft)} \\ L_u = L_v = 145h^{1/3} \\ \text{For } 100 < h < 1750 \text{ (ft)} \\ L_w = h \\ \text{For } h \leq 100 \text{ (ft)} \\ L_w = 100 \end{aligned} \tag{A-44}$$

The intensities and scale lengths are related as follows

$$\frac{\sigma_u^2}{L_u} = \frac{\sigma_v^2}{L_v} = \frac{\sigma_w^2}{L_w} \tag{A-45}$$

In addition, the equivalent gust angles of attack and sideslip have spectra given by

# Contrails

$$\begin{aligned}\phi_{\alpha}(\Omega) &= \frac{1}{U^2} \phi_w(\Omega) \\ \phi_{\beta}(\Omega) &= \frac{1}{U^2} \phi_v(\Omega)\end{aligned}\tag{A-46}$$

The relative airspeed of the aircraft as it passes through the gust field defines a transformation from the spatial frequency to the temporal frequency as given by the equation

$$\phi(\omega) = \frac{1}{U} \phi(\Omega=\omega/U)\tag{A-47}$$

These equations are sufficient to describe the gust model for an aircraft in wings-level, horizontal flight. However, for altitudes below 1750 ft, where the gust field is anisotropic, either a significant climb angle or bank angle will alter the vertical and horizontal gust intensities along the respective body axes. For this study the change for non-zero climb angle was neglected, but transformed intensities were calculated for banked flight using the following equations, where the subscript "b" indicates the banked flight intensity

$$\begin{aligned}\sigma_{u_b} &= \sigma_u \\ \sigma_{v_b}^2 &= \sigma_w^2 \sin^2 \phi_o + \sigma_v^2 \cos^2 \phi_o \\ \sigma_{w_b}^2 &= \sigma_w^2 \cos^2 \phi_o + \sigma_v^2 \sin^2 \phi_o\end{aligned}\tag{A-48}$$

Banked flight scale lengths were then obtained from Equation (A-45)

One additional change was adopted. For the terminal approach task near an altitude of 100 ft the values of  $\sigma_u$  and  $\sigma_v$  as determined from these equations for severe turbulence were deemed excessive.<sup>17</sup> Instead of the calculated values of about 16 ft/sec a value of 10 ft/sec was used.

In order to incorporate the gust model into the state-vector equations of the system, equivalent gust state-vector differential equations were derived following the approach of Heath.<sup>27</sup> The procedure was to use the Dryden model spectral factors as presented in Reference 18 as the system transfer function for each gust variable, then to derive the equivalent differential equations.

Before continuing we note that the variance for each gust variable (i.e., the mean square intensity) is defined by the following integral in the Reference 18 gust model

$$\sigma^2 = \int_0^{\infty} \phi(\omega) d\omega \quad (\text{A-49})$$

This integral must be transformed to correspond to the standard definition of the variance as given in Reference 28 in order that further stochastic analysis will be consistent

$$\sigma^2 = \frac{1}{\pi} \int_0^{\infty} \phi^*(\omega) d\omega = \frac{1}{\pi} \int_0^{\infty} \pi \phi(\omega) d\omega \quad (\text{A-50})$$

Thus  $\phi^*(\omega) = \pi \phi(\omega)$ , where  $\phi(\omega)$  is the power spectral density given for the Dryden model and  $\phi^*(\omega)$  is the scaled equivalent

Dryden spectrum corresponding to the standard definition of the variance.

As an example of the method, the derivation of the state-vector equation for the equivalent gust angle-of-attack is shown. The spectral factor for  $\alpha_g$  is obtained from Reference 18 and scaled by the factor  $\sqrt{\pi}$  in accordance with Equation (A-50).

$$T_{\alpha_g}^*(s) = \frac{\sigma_w}{U} \sqrt{\frac{L_w}{U}} \frac{1 + \sqrt{3} \frac{L_w}{U} s}{\left(1 + \frac{L_w s}{U}\right)^2} \quad (\text{A-51})$$

For convenience this is rewritten as

$$T_{\alpha_g}^*(s) = K \frac{(s+a)}{(s+b)^2} \quad (\text{A-52})$$

where

$$K = \frac{\sigma_w}{U} \sqrt{\frac{3U}{L_w}} \quad a = \frac{U\sqrt{3}}{3L_w} \quad b = U/L_w \quad (\text{A-53})$$

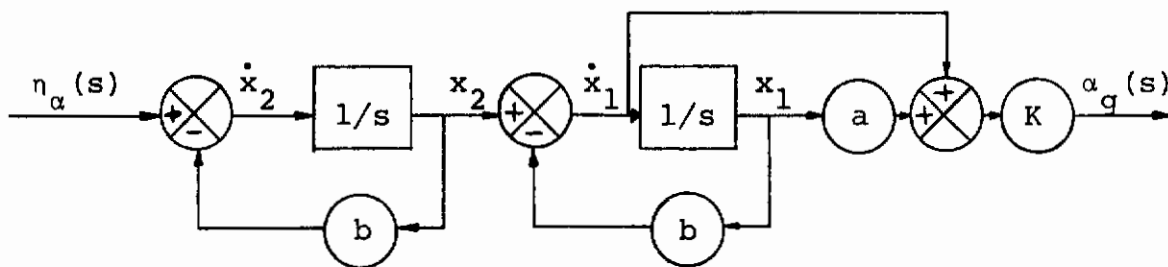

The "iterative programming" approach<sup>29</sup> to obtaining the equivalent system of differential equations is now employed.

Rewriting the transfer function as

$$T_{\alpha_g}^*(s) = \frac{1}{s+b} \frac{s+a}{s+b} \quad K = \frac{1/s}{1+b/s} \frac{1+a/s}{1+b/s} \quad K \quad (\text{A-54})$$

We can write the equivalent block diagram assuming an input  $\eta_\alpha(s)$  (a unit spectrum Gaussian white noise).

# Controls

By inspection of this diagram the differential and output equations are found to be

$$\begin{aligned} \dot{x}_1 &= -bx_1 + x_2 & \alpha_g &= Kax_1 + Kx_2 - Kbx_1 = \\ \dot{x}_2 &= -bx_2 + \eta_\alpha & &= K(a-b)x_1 + Kx_2 \end{aligned} \quad (A-55)$$

In order to introduce  $\alpha_g$  as a state variable we differentiate the output expression

$$\begin{aligned} \dot{\alpha}_g &= K(a-b)\dot{x}_1 + K\dot{x}_2 \\ &= K(a-b)(-bx_1+x_2) + K(-bx_2+\eta_\alpha) \\ &= -b[K(a-b)x_1+Kx_2] + K(a-b)x_2 + K\eta_\alpha \\ &= -b\alpha_g + K(a-b)x_2 + K\eta_\alpha \end{aligned} \quad (A-56)$$

Defining  $\alpha'_g = x_2$  and replacing the values of the constants we obtain

$$\begin{aligned} \dot{\alpha}_g &= -\frac{U}{L_w} \alpha_g + (1-\sqrt{3})\frac{\sigma_w}{L_w}\sqrt{\frac{U}{L_w}} \alpha'_g + \frac{\sigma_w}{U}\sqrt{\frac{3U}{L_w}} \eta_\alpha \\ \dot{\alpha}'_g &= -\frac{U}{L_w} \alpha'_g + \eta_\alpha \end{aligned} \quad (A-57)$$

The form of the spectral factor for the gust sideslip angle is identical to the gust angle-of-attack; thus, we obtain the

gust sideslip equations by substituting  $\sigma_v$  and  $L_v$  in Equation (A-57)

$$\begin{aligned}\dot{\beta}_g &= -\frac{U}{L_v} \beta_g + (1-\sqrt{3}) \frac{\sigma_v}{L_v} \sqrt{\frac{U}{L_v}} \beta'_g + \frac{\sigma_v}{U} \sqrt{\frac{3U}{L_v}} \eta_\beta \\ \dot{\beta}'_g &= -\frac{U}{L_v} \beta'_g + \eta_\beta\end{aligned}\tag{A-58}$$

The spectral factors for the gusts  $u_g$  and  $p_g$  represent first order differential equations given by

$$\dot{u}_g = -\frac{U}{L_u} u_g + \frac{\sigma_u}{U} \sqrt{\frac{2U}{L_u}} \eta_u\tag{A-59}$$

and

$$\dot{p}_g = -\left(\frac{\pi U}{4b}\right) p_g + \frac{\pi \sigma_w}{4b} \sqrt{\left(\frac{\pi U}{L_w}\right) 0.8 \left(\frac{\pi L_w}{4b}\right)^{1/3}} \eta_p\tag{A-60}$$

Reference 27 also presents the equations for  $q_g$  and  $r_g$ . However, in this analysis  $q_g$  and  $r_g$  were replaced by their equivalent expressions in terms of  $\dot{\alpha}_g$  and  $\dot{\beta}_g$ . This special form made the next step necessary. In order to introduce this state-vector gust model into the total system model it was necessary to substitute  $\dot{\alpha}_g$  and  $\dot{\beta}_g$  into the equations for  $\dot{\alpha}$ ,  $\dot{q}$ ,  $\dot{p}$ , and  $\dot{r}$  of Equations (A-29). Considering only the terms involving these gust derivatives, we obtained for  $\dot{\alpha}$

# Controls

$$\begin{aligned}
 f_2 f_3 (C_{z_q} - C_{z_\alpha}) \dot{\alpha}_g &= -f_2 f_3 (C_{z_q} - C_{z_\alpha}) \frac{U}{L_w} \alpha_g + \\
 & f_2 f_3 (C_{z_q} - C_{z_\alpha}) (1 - \sqrt{3}) \frac{\sigma_w}{L_w} \sqrt{\frac{U}{L_w}} \alpha'_g + \\
 & f_2 f_3 (C_{z_q} - C_{z_\alpha}) \frac{\sigma_w}{U} \sqrt{\frac{3U}{L_w}} \eta_\alpha \quad (A-61)
 \end{aligned}$$

For  $\dot{q}$

$$\begin{aligned}
 f_y f_8 [C_{m_q} - C_{m_\alpha} + f_2 f_3 C_{m_\alpha} (C_{z_q} - C_{z_\alpha})] \dot{\alpha}_g &= \\
 & -f_y f_8 [C_{m_q} - C_{m_\alpha} + f_2 f_3 C_{m_\alpha} (C_{z_q} - C_{z_\alpha})] \frac{U}{L_w} \alpha_g + \\
 & f_y f_8 [C_{m_q} - C_{m_\alpha} + f_2 f_3 C_{m_\alpha} (C_{z_q} - C_{z_\alpha})] (1 - \sqrt{3}) \frac{\sigma_w}{L_w} \sqrt{\frac{U}{L_w}} \alpha'_g + \\
 & f_y f_8 [C_{m_q} - C_{m_\alpha} + f_2 f_3 C_{m_\alpha} (C_{z_q} - C_{z_\alpha})] \frac{\sigma_w}{U} \sqrt{\frac{3U}{L_w}} \eta_\alpha \quad (A-62)
 \end{aligned}$$

For  $\dot{p}$

$$\begin{aligned}
 -(C_{l_{r_g}}) \dot{\beta}_g &= C_{l_{r_g}} \frac{U}{L_v} \beta_g - C_{l_{r_g}} (1 - \sqrt{3}) \frac{\sigma_v}{L_v} \sqrt{\frac{U}{L_v}} \beta'_g - \\
 & C_{l_{r_g}} \frac{\sigma_v}{U} \sqrt{\frac{3U}{L_v}} \eta_\beta \quad (A-63)
 \end{aligned}$$

And for  $\dot{r}$

$$\begin{aligned}
 -(C_{n_{r_g}}) \dot{\beta}_g &= C_{n_{r_g}} \frac{U}{L_v} \beta_g - C_{n_{r_g}} (1 - \sqrt{3}) \frac{\sigma_v}{L_v} \sqrt{\frac{U}{L_v}} \beta'_g - \\
 & C_{n_{r_g}} \frac{\sigma_v}{U} \sqrt{\frac{3U}{L_v}} \eta_\beta \quad (A-64)
 \end{aligned}$$

# Contrails

Next, the coefficients of  $\alpha_g$  and  $\beta_g$  from these equations were combined with the coefficients from Equations (A-29). When the indicated summations were accomplished the total contributions to the  $\dot{\alpha}$ ,  $\dot{q}$ ,  $\dot{p}$  and  $\dot{r}$  equations due to gusts were as follows

$$\begin{aligned} \dot{\alpha} = & \dots - (f_1 f_3 C_{z_u}) \frac{u_g}{U} - [f_1 f_3 C_{z_\alpha} + f_2 f_3 (C_{z_q} - C_{z_\alpha}) \frac{U}{L_w}] \alpha_g + \\ & f_2 f_3 (C_{z_q} - C_{z_\alpha}) (1-\sqrt{3}) \frac{\sigma_w}{L_w} \sqrt{\frac{U}{L_w}} \alpha'_g + \\ & f_2 f_3 (C_{z_q} - C_{z_\alpha}) \frac{\sigma_w}{U} \sqrt{\frac{3U}{L_w}} \eta_\alpha \end{aligned} \quad (A-65)$$

$$\begin{aligned} \dot{q} = & \dots - f_y (C_{m_u} + f_2 f_3 C_{m_\alpha} C_{z_u}) \frac{u_g}{U} - \\ & \{f_y (C_{m_\alpha} + f_2 f_3 C_{m_\alpha} C_{z_\alpha}) + f_y f_8 [C_{m_q} - C_{m_\alpha} + f_2 f_3 C_{m_\alpha} (C_{z_q} - C_{z_\alpha})] \frac{U}{L_w}\} \alpha_g + \\ & f_y f_8 [C_{m_q} - C_{m_\alpha} + f_2 f_3 C_{m_\alpha} (C_{z_q} - C_{z_\alpha})] (1-\sqrt{3}) \frac{\sigma_w}{L_w} \sqrt{\frac{U}{L_w}} \alpha'_g + \\ & f_y f_8 [C_{m_q} - C_{m_\alpha} + f_2 f_3 C_{m_\alpha} (C_{z_q} - C_{z_\alpha})] \frac{\sigma_w}{U} \sqrt{\frac{3U}{L_w}} \eta_\alpha \end{aligned} \quad (A-66)$$

$$\begin{aligned} \dot{p} = & \dots - (f_x C_{l_\beta}' - C_{l_{r_g}} \frac{U}{L_v}) \beta_g - C_{l_{r_g}} (1-\sqrt{3}) \frac{\sigma_v}{L_v} \sqrt{\frac{U}{L_v}} \beta'_g - \\ & (f_6 C_{l_p}') p_g - C_{l_{r_g}} \frac{\sigma_v}{U} \sqrt{\frac{3U}{L_v}} \eta_\beta \end{aligned} \quad (A-67)$$

$$\begin{aligned} \dot{r} = & \dots - (f_z C_{n_\beta}' - C_{n_{r_g}} \frac{U}{L_v}) \beta_g - C_{n_{r_g}} (1-\sqrt{3}) \frac{\sigma_v}{L_v} \sqrt{\frac{U}{L_v}} \beta'_g - \\ & (f_7 C_{n_p}') p_g - C_{n_{r_g}} \frac{\sigma_v}{U} \sqrt{\frac{3U}{L_v}} \eta_\beta \end{aligned} \quad (A-68)$$

# Contrails

As a check on the numerical results it is useful to have analytical expressions for the gust variances. The laborious derivation of these variances was performed by the author and Heath<sup>27</sup> jointly. The integral definition for each variance was evaluated both by residue theory and Phillips Integral formulas resulting in the following equations

$$\begin{aligned}\sigma_{u_g} &= \sigma_u & \sigma_{\alpha_g}^2 &= (\sigma_w/U)^2 & \sigma_{\beta_g}^2 &= (\sigma_v/U)^2 \\ \sigma_{p_g}^2 &= \frac{\pi^2 \sigma_w^2}{10bL_w} \left(\frac{\pi L_w}{4b}\right)^{1/3} & \sigma_{q_g}^2 &= \frac{\pi \sigma_w^2}{8b} \frac{3L_w + 8b/\pi}{(L_w + 4b/\pi)^2} \\ \sigma_{r_g}^2 &= \frac{\pi \sigma_v^2}{2b} \frac{L_v + 2b/\pi}{(L_v + 3b/\pi)^2}\end{aligned}\tag{A-69}$$

## Flight Director Equations

Since it was not the intent of this study to design an optimum flight director a very simple display was provided for the pilot. The exact format of the display was not specified, but it could be considered for this analysis to consist of two perpendicular cross pointers which translate with respect to a fixed reference on a single display device. The horizontal pointer moves up and down to provide a longitudinal flight path error signal, which the pilot attempts to null by elevator command inputs. This longitudinal error signal  $y_L$  is given by the linearized equation

$$y_L = (\cos\phi_0)\theta + (\sin\phi_0)\psi + K_{d_z} \dot{d}_z \quad (A-70)$$

The vertical pointer moves sideways to provide a lateral-directional flight path error signal, which the pilot must null by aileron command inputs. This error signal  $y_{LD}$  is given by

$$y_{LD} = -\phi - (K_\psi \cos\phi_0)\psi + (K_\psi \sin\phi_0)\theta - K_{d_y} \dot{d}_y \quad (A-71)$$

The signs and the gains,  $K_{d_z}$ ,  $K_\psi$ , and  $K_{d_y}$ , in these equations were chosen primarily to stabilize the system with little effort devoted to system optimization. It should be noted that this flight director combines the aircraft attitude and path error signals into a single display which provides the pilot with a "compensatory" tracking task. Only state feedback compensation was included in this design. In actual practice, washout filters would be required to allow steady-state non-zero pitch and roll attitude angles. In addition, other compensation could be used to reduce the pilot workload. For this linear analysis these effects were neglected.

As will be discussed in the following section on the mathematical pilot model, the human pilot can perceive both the error signal and its time derivative. To obtain this derivative we differentiated Equations (A-70) and (A-71) to give the following

$$\dot{y}_L = -(K_{d_z} U) \alpha + q + (K_{d_z} U \cos\phi_0) \dot{\theta} - (\dot{\psi}_0 \cos\phi_0) \dot{\phi} + (K_{d_z} U \sin\phi_0) \dot{\psi} \quad (A-72)$$

$$\dot{Y}_{LD} = (K_{dY} U \sin \phi_o - \dot{\Psi}_o) \theta - (K_{\psi} / \cos \theta_o + \tan \theta_o) r - p - (K_{dY} U) \beta - (K_{\psi} \dot{\Psi}_o \sin \phi_o) \phi - (K_{dY} U \cos \theta_o \cos \phi_o) \psi \quad (A-73)$$

### Human Pilot Model Equations

In this analysis the human pilot was represented by a somewhat simplified version of the "quasi-linear" describing function presented in detail in Reference 4. In the detailed model the pilot parameters are adjusted in such a manner that certain minimum stability margins are maintained when possible. This adjustment was not considered in this analysis.

Two alternate forms of the linear model were investigated. The first consisted of a pilot gain, lead, lag, and a pure time delay represented as follows in block diagram form

where  $\delta_p$  is the pilot commanded control output and  $y$  is the input error signal. The first order Pade approximation was used to linearize the pure time delay and obtain the total pilot transfer function

$$\frac{\delta_p}{y}(s) = - \frac{K_p (T_L s + 1) (s - 2/\tau)}{(T_I s + 1) (s + 2/\tau)} \quad (A-74)$$

# Contrails

This can readily be expressed in state-vector form following the procedure in the section on gust models. These equivalent time-domain equations are given in Reference 30. They are

$$\begin{aligned}\dot{x}_{p_1} &= -(2/\tau)x_{p_1} + (4/\tau)x_{p_2} \\ \dot{x}_{p_2} &= -\frac{1}{T_1}x_{p_2} + \frac{K_p T_L}{T_1}\dot{y} + \frac{K_p}{T_1}y\end{aligned}\tag{A-75}$$

$$\delta_p = x_{p_1} - x_{p_2}$$

where  $y$  and  $\dot{y}$  come from the flight director equations.

The alternate pilot model was identical to the first, except that the lag was zero. The state-vector equations for this model are

$$\begin{aligned}\dot{x}_p &= -(2/\tau)x_p + (4K_p T_L/\tau)\dot{y} + (4K_p/\tau)y \\ \delta_p &= x_p - K_p T_L \dot{y} - K_p y\end{aligned}\tag{A-76}$$

Some studies, which are more recent than Reference 4, have used a concept commonly called "paper pilot"<sup>5, 6, 7, 8</sup> to select the pilot parameters using state-vector optimal control techniques. The approach used in this analysis was similar to those studies in the sense that it assumes that the pilot will adjust his parameters in such a fashion that he will minimize a quadratic performance index which includes the error signal the pilot actually perceives.

# Contrails

The models of Equations (A-75) and (A-76) are single-input/single-output models. Thus, two sets of the equations were required in this analysis: one for the longitudinal mode and one for the lateral-directional mode.

Pilot remnant was added to both the longitudinal and lateral-directional pilot models. The remnant was assumed to be a first-order filtered Gaussian white noise process introduced at the control wheel where it is a part of the pilot's commanded control output. As shown in Reference 17 the remnant power spectral density is

$$\phi_{nn}(\omega) = \frac{(1-\eta_e)}{\omega_s} \frac{\sigma_y^2}{[1+(\frac{\omega T_{de}}{2})^2]} \quad (A-77)$$

The equivalent state-vector differential equation is as follows (where the spectrum has been scaled by the factor  $\pi$  according to Equation (A-50))

$$\dot{n}_\delta = -\omega_R n_\delta + \sigma_y \sqrt{\pi K_R} \eta_n \quad (A-78)$$

The remnant introduces two additional state variables,  $n_{\delta_e}$  and  $n_{\delta_a}$  to represent elevator command remnant and aileron command remnant; where  $\eta_{n_e}$  and  $\eta_{n_a}$  are unit spectrum Gaussian white noise inputs; and where  $\omega_R = 2/T_{d_e}$  and  $K_R = (2/T_{d_e})^2 (1-\eta_e)/\omega_s$ . The values of  $\omega_R$  and  $K_R$  for each mode can be obtained by using the values in Table XXII of Reference 17.

Because the remnant is introduced at the control wheel  $\sigma_y$  is actually  $\sigma_{u_p}$  where

$$u_p = K_p y + K_p T_L \dot{y} \quad (\text{A-79})$$

which is a linear combination of the observation terms appearing in the quasi-linear pilot model equations.

We note that  $\sigma_y$  is an rms output variable of the set of stochastic differential equations. As a result, the covariance calculation has been transformed to an iterative procedure starting with an initial guess for  $\sigma_y$  and terminating when  $\sigma_y$  converges to a constant. This represents a costly increase in computer time, and in actual practice two or three iterations were used at most.

## State-Vector Stability Augmentation

In this analysis various stability augmentation system (SAS) configurations were analyzed to determine their effect upon the piloted system gust response. However, each configuration consisted of a combination of pure state feedback with appropriate gains. No dynamic compensation was used. The feedback was, in general, "incomplete" state feedback and was specified in a manner such that the gains could be distributed across the states in pre-selected modes in accordance with the following equations

$$\begin{aligned} \dot{x} &= Ax + Bu \\ y &= (C_1 + C_2 A)x \\ u &= Hy \end{aligned} \quad (\text{A-80})$$

# Contrails

where  $x$  was the vector of aircraft states for the mode for which SAS was being designed;  $u$  was the vector of SAS control commands such that  $u' = [\delta_{e_s}, \delta_{T_s}, \delta_{a_s}, \delta_{r_s}]$ ;  $y$  was the vector of observations of the aircraft states;  $C = (C_1 + C_2A)$  was the observation matrix; and  $H$  was the matrix of adjustable stability augmentation gains.

The closed loop augmented system equation was then

$$\dot{x} = (A + BHC)x = [A + BH(C_1 + C_2A)]x \quad (A-81)$$

Actually, the pilot commands also drove the elevator and aileron actuators such that the actuator commands of Equation (A-34) were given by

$$\begin{aligned} \delta_{e_c} &= \delta_{e_p} + n_{\delta_e} + \delta_{e_s} \\ \delta_{a_c} &= \delta_{a_p} + n_{\delta_a} + \delta_{a_s} \end{aligned} \quad (A-82)$$

## Trim Equations

Two special trim conditions were chosen for analysis in this study. As mentioned before, these were the following: wings-level descending flight, which is representative of an aircraft in the final landing approach condition; and horizontal banked flight, which is representative of a maneuvering aircraft following a curved landing approach path.

At this point it is appropriate to review the simplifying assumptions which were made during the derivation of the linearized small perturbation equations for these two flight conditions. First, the motion was assumed to be referenced

to the airmass. However, we recall that the air was not assumed to be rotating; thus, angular velocities can be considered either air or ground referenced. Second, the airmass was assumed to have constant velocity except for variations with altitude (wind gradients). Thus, for the horizontal banked turn no additional accelerations of the air must be considered.

Reviewing the assumed trim values, we note that to obtain Equations (A-10) we let  $P_o = \dot{\theta}_o = W_o = V_o = 0$ . Since the airmass was the chosen reference, this means that  $W_o$  and  $V_o$  are air reference velocities. In other words, the trim x-axis was chosen to be aligned with the total trim "airspeed" vector. Simplifying to horizontal banked flight, we set  $\theta_o = 0$ , or simplifying to descending flight, we set  $\phi_o = \dot{\psi}_o = Q_o = R_o = 0$ . Notice that although we think of "trim points" as being "unaccelerated" flight conditions it was not necessary to make any assumptions about the linear trim accelerations ( $\dot{U}_o, \dot{V}_o, \dot{W}_o$ ) for either trim condition. We are then free to choose these values arbitrarily in order to establish a flight path that approximates an actual specified landing approach condition in the presence of wind.

The procedure for trimming the aircraft that was used in this analysis was as complete as the available aerodynamic and thrust data would allow. Since no moment data was available the aircraft was trimmed using only the three force equations, Equations (A-1), and the Euler equations, Equations (A-4). In order to include the wind in the trim

# Contrails

calculations the inertial reference was shifted back to the ground. Then, for the aircraft heading angle,  $\psi_o$ , and the angle from which the wind blows,  $\psi_{w_o}$ , both measured clockwise from the North, the wind components for horizontal flight became

$$\begin{aligned}U_w &= -|\bar{V}_w| \sin(\psi_{w_o} - \psi_o) \\V_w &= -|\bar{V}_w| \cos(\psi_{w_o} - \psi_o)\end{aligned}\tag{A-83}$$

where  $\bar{V}_w$  is the total wind velocity vector.

For banked flight these were transformed by the Euler roll angle  $\phi_o$  such that

$$\begin{aligned}V_w &= -|\bar{V}_w| \cos(\psi_{w_o} - \psi_o) \cos \phi_o \\W_w &= -|\bar{V}_w| \cos(\psi_{w_o} - \psi_o) \sin \phi_o\end{aligned}\tag{A-84}$$

For descending flight the aircraft experiences accelerations due to the vertical wind gradient,  $d\bar{V}_w/dh$ , as follows

$$\begin{aligned}\dot{U}_w &= -\left|\frac{d\bar{V}_w}{dh}\right| U \sin \theta_o \cos(\psi_{w_o} - \psi_o) \cos \theta_o \\ \dot{W}_w &= -\left|\frac{d\bar{V}_w}{dh}\right| U \sin \theta_o \cos(\psi_{w_o} - \psi_o) \sin \theta_o\end{aligned}\tag{A-85}$$

For descending flight we assumed the air referenced accelerations were zero ( $\dot{U}_o = \dot{V}_o = \dot{W}_o = 0$ ). Then  $U = U_o + U_w$ ,  $V = V_w$ ,  $W = W_w$ , and  $\dot{U} = \dot{U}_w$ ,  $\dot{V} = \dot{V}_w$ , and  $\dot{W} = \dot{W}_w$ . In addition, we only considered wind gradients along the flight path and neglected the side force equation, since no trim data was available for

# Contrails

steady sideslip and the linearized equations did not include a non-zero  $V_o$  or  $\phi_o$ . Equations (A-1) then became

$$\begin{aligned}F_x &= -\bar{C}_D qS - mg \sin \theta_o = m \dot{U}_w \\F_z &= mg \cos \theta_o - C_L qS = m \dot{W}_w\end{aligned}\tag{A-86}$$

where  $\bar{C}_D$  includes both thrust and drag effects. These were solved for the lift and drag coefficients

$$\begin{aligned}C_L &= \frac{mg \cos \theta_o - m \dot{W}_w}{qS} \\ \bar{C}_D &= \frac{mg \sin \theta_o - m \dot{U}_w}{qS}\end{aligned}\tag{A-87}$$

For banked flight the wind velocity components change because of the turn rate, but for this case we assumed that the turn was negotiated in a manner such that the total linear accelerations in the body axes were zero ( $\dot{U}=\dot{V}=\dot{W}=0$ ).

Equations (A-1) then became

$$\begin{aligned}F_x &= -\bar{C}_D qS = m(W_w Q_o - V_w R_o) \\F_y &= mg \sin \phi_o = m(U_o + U_w) R_o \\F_z &= mg \cos \phi_o - C_L qS = m(-U_o - U_w) Q_o\end{aligned}\tag{A-88}$$

and the Euler Equations (A-4) became

$$\begin{aligned}\dot{\phi}_o &= P_o = 0 \\Q_o &= \dot{\psi}_o \sin \phi_o \\R_o &= \dot{\psi}_o \cos \phi_o\end{aligned}\tag{A-89}$$

These were solved for the lift and drag coefficients and the steady bank angle.

$$\begin{aligned}\bar{C}_D &= \frac{m}{qS} (V_w R_o - W_w Q_o) \\ C_L &= \frac{m}{qS} [g \cos \phi_o + (U_o + U_w) Q_o] \\ \phi_o &= \tan^{-1} \left[ \frac{\dot{\psi}_o (U_o + U_w)}{g} \right]\end{aligned}\tag{A-90}$$

### Aerodynamic and Thrust Data

The aerodynamic and thrust data used in this analysis was taken from reports on the Breguet 941/McDonnell Douglas 188 STOL aircraft. The primary data sources were the same as those for Reference 3. Most of the stability derivatives came from computer program listings for a NASA Ames Research Center simulation of the Breguet. The remainder were calculated using the parametric curves in Reference 23. The constant stability derivatives and parameters are listed in Table A.1. The variable derivatives depended upon the trim  $C_L$  and  $\bar{C}_D$ . These were calculated from formulas derived in the manner of those in Reference 22, paragraph 1-7, where for the Breguet  $\bar{C}_D = C_D - T'_C$  and  $T'_C = T/(qS)$ .

$$\begin{aligned}\frac{\partial T'_C}{\partial u} &= \left( \frac{1}{qS} \frac{\partial T}{\partial u} - \frac{2T'_C}{U} \right) \\ C_{x_u} &= -2\bar{C}_D + \alpha \frac{\partial \bar{C}_D}{\partial \alpha} - \frac{\partial \bar{C}_D}{\partial T'_C} U \frac{\partial T'_C}{\partial u} \\ C_{z_u} &= -2C_L + \alpha \frac{\partial C_L}{\partial \alpha} - \frac{\partial C_L}{\partial T'_C} U \frac{\partial T'_C}{\partial u}\end{aligned}$$

Table A.1

Breguet 941 Constants and Stability Derivatives

Constants

 C_{z_{\delta_T}} &= - \frac{\partial C_L}{\partial T_c'} \left( \frac{1}{qS} \frac{\partial T}{\partial p} \right) \frac{c_p}{\delta_T} \\
 C_{m_{\delta_T}} &= \frac{UI_{yy}}{qScW} M_{T_c} \left( \frac{1}{qS} \frac{\partial T}{\partial p} \right) \frac{c_p}{\delta_T} \tag{A-91}
 \end{aligned}$$

where  $\alpha$ ,  $T_c'$ ,  $\partial \bar{C}_D / \partial \alpha$ ,  $\partial \bar{C}_D / \partial T_c'$ ,  $\partial C_L / \partial \alpha$ , and  $\partial C_L / \partial T_c'$  were determined by linear interpolation and differentiation of the curves of Figures 29 and 30 of Reference 23. These curves were digitized and stored as tables for rapid calculations. The additional curves of engine thrust versus power for 90 and 95 percent propeller rpm were taken from pages 3.9 and 3.10 of the supplement to Reference 23. These were used to compute  $\partial T / \partial P$ . The factor  $c_p / \delta_T$  was introduced to scale full throttle deflection to 1200 horsepower.

Some small differences in the numerical values of the longitudinal stability derivatives between this analysis and those of References 3 and 10 may be explained by the fact that in this study the angle of attack data from Figure 30 of

# *Contrails*

Reference 23 was used to correct all values from indicated to actual angle of attack.

Appendix B  
Optimal Incomplete Feedback Control of  
Infinite Time Linear Stochastic Systems

Heath<sup>21</sup> derived the necessary conditions that the optimal control law must satisfy for both the finite and infinite time problems. The gradient derived for the infinite time problem was used to develop a computer program for calculation of the fixed gain control matrix. A summary of the applicable equations from Reference 21 are presented here. The infinite time problem is described and the gradient equations employed in the computer program are presented. In order to make the computer algorithm more efficient the covariance and adjoint gain equations were partitioned. Heath showed the partitioning for his example problem, but the program was revised to handle the different partitioning required in this study, and the revised equations are presented here.

Problem Formulation

The equivalent time-invariant linear system stochastic differential equation is

$$\begin{aligned} dx(t,r,\omega) &= A(r)x(t,r,\omega)dt + B(r)u(t,r,\omega)dt + \\ &\quad M(r)d\beta(t,\omega) \\ x(t_0,r,\omega) &= x_0(\omega) \quad \text{for all } r \in \Omega_1 \end{aligned} \quad (B-1)$$

where  $\Omega_1$  is the domain of  $r$  in the associated probability

space.

The observation is

$$y(t, r, \omega) = C(r)x(t, r, \omega) \quad (B-2)$$

The infinite time linear stochastic system optimal incomplete feedback control problem is then to find the fixed gain control matrix  $H \in R^{m \times 1}$  such that

$$u_h(t, r, \omega) = -Hy(t, r, \omega) \quad (B-3)$$

minimizes

$$J(H) = \frac{1}{2} \lim_{t \rightarrow \infty} \int_{\Omega_1} \int_{\Omega_2} [x_h'(t, r, \omega) Q x_h(t, r, \omega) + u_h'(t, r, \omega) R u_h(t, r, \omega)] d\omega dr \quad (B-4)$$

where  $\Omega_2$  is the domain of  $\omega$  in the associated probability space, subject to the stochastic integral constraint

$$x_h(t, r, \omega) = x_0(\omega) + \int_{t_0}^t M(r) d\beta(s, \omega) + \int_{t_0}^t [A(r) - B(r)HC(r)] x_h(s, r, \omega) d\omega dr \quad (B-5)$$

where Equation (B-5) is an integral representation of the Stochastic Differential Equation (B-1) after substituting the feedback control; and where  $x_0$  is an  $n$ -dimensional  $\Omega_2$  random variable with covariance

$$\int_{\Omega_2} x_0(\omega) x_0'(\omega) d\omega = P_0 \quad (B-6)$$

$\beta$  is an  $r$ -dimensional Wiener process with covariance

$$\int_{\Omega_2} [\beta(t, \omega) - \beta(s, \omega)][\beta(t, \omega) - \beta(s, \omega)]' d\omega = (t-s)W \quad (B-7)$$

where  $W$  is a positive definite matrix; and  $x_0$  and  $\beta$  are independent such that

$$\int_{\Omega_2} x_0(\omega) \beta'(t, \omega) d\omega = 0 \quad (B-8)$$

for all  $r \in \Omega_1$ ,  $A(r) \in R^{n \times n}$ ,  $R \in R^{m \times m}$ ,  $H \in R^{m \times 1}$ ,  $Q \in R^{n \times n}$ , and  $R$  and  $Q$  are symmetric positive semi-definite.

The reader should consult Reference 21 for further definitions and assumptions and for the rigorous development of the necessary conditions and the gradient equations.

### Gradient Equations for Discrete Events

Theorem 4.3.1 from Reference 21 summarizes the gradient equations for the special case actually implemented on the computer. According to this theorem:

if the probability space  $\Omega_1$  consists of  $N$  separate events, the  $i$ th event having probability  $p_i$ , then the optimal control matrix  $H$  satisfies

$$\nabla J(H) = \sum_{i=1}^N [RHC_i - B_i'K_i]P_i C_i' p_i = 0 \quad (B-9)$$

where

$$[A_i - B_i H C_i] P_i + P_i [A_i - B_i H C_i]' + M_i W M_i' = 0 \quad (B-10)$$

$$[A_i - B_i H C_i]' K_i + K_i [A_i - B_i H C_i] + Q + C_i' H' R H C_i = 0 \quad (B-11)$$

where  $K_i$  is the gain adjoint matrix for the  $i$ th system.

Theorem 4.3.2 of Reference 21 also presents the equations for the special case of a probability space  $\Omega_1$  consisting of a single event:

$$\nabla J(H) = (RHC - B'K)PC' \quad (B-12)$$

where

$$(A-BHC)P + P(A-BHC)' + MWM' = 0 \quad (B-13)$$

$$(A-BHC)'K + K(A-BHC) + Q + C'H'RHC = 0 \quad (B-14)$$

These equations for a single event are all that were employed in this analysis.

#### Computer Algorithm

For implementation of the computer program the performance index was generalized as follows by Heath

$$J(H) = \int_{\Omega} \sum_{i=1}^N \lim_{t \rightarrow \infty} [z(t, r_i, \omega)' Q z(t, r_i, \omega)] p_i d\omega \quad (B-15)$$

where

$$z(t, r_i, \omega) = D(r_i)x(t, r_i, \omega) + T(r_i)u(t, r_i, \omega) \quad (B-16)$$

For systems analyzed in this study the Covariance Equation (B-13) was partitioned in a manner which necessarily differed from the example shown by Heath. The feedback matrix had the same partitioning

$$F = A - BHC = \begin{bmatrix} F_{11} & F_{12} \\ 0 & F_{22} \end{bmatrix} \quad (B-17)$$

but the stochastic input coefficient matrix was partitioned with non-zero upper elements

$$M = \begin{bmatrix} M_1 \\ M_2 \end{bmatrix} \quad (B-18)$$

Then the covariance equation became

$$\begin{bmatrix} F_{11} & F_{12} \\ 0 & F_{22} \end{bmatrix} \begin{bmatrix} P_{11} & P_{12} \\ P'_{12} & P_{22} \end{bmatrix} + \begin{bmatrix} P_{11} & P_{12} \\ P'_{12} & P_{22} \end{bmatrix} \begin{bmatrix} F_{11} & 0 \\ F'_{12} & F_{22} \end{bmatrix} + \begin{bmatrix} M_1 \\ M_2 \end{bmatrix} W [M'_1, M'_2] = 0 \quad (B-19)$$

After performing the indicated matrix multiplications and additions the following three equations were obtained

$$F_{22}P_{22} + P_{22}F'_{22} + M_2WM'_2 = 0 \quad (B-20)$$

$$F_{11}P_{12} + P_{12}F'_{12} + F_{12}P_{22} + M_1WM'_2 = 0 \quad (B-21)$$

$$F_{11}P_{11} + P_{11}F'_{11} + F_{12}P'_{12} + P_{12}F'_{12} + M_1WM'_1 = 0 \quad (B-22)$$

Solution of these partitioned equations is significantly more efficient than direct solution of Equation (B-13).

An additional change in the computer algorithm was the inclusion of a gradient transformation which could be employed at the user's option to accelerate the convergence to a solution. This transformation equivalently circularized the performance index contours. There exists a tradeoff between the loss of accuracy by introduction of the transformation

and the potential benefit of a reduction in solution time for non-circular contour problems. The user must determine the significance of this tradeoff for his particular problem. In this analysis the gradient transform was used for the state-vector SAS design, but it was not used during the calculation of the pilot gains.

## Appendix C Transfer Functions for Frequency Analysis

A set of computer subroutines were developed to calculate system transfer functions directly from the system equations in state-vector form. The transfer functions were used for several tasks: e.g., validation comparison of the basic airframe transfer functions using other computer programs, e.g., McGlynn,<sup>32</sup> initial selection of flight-director system gains, and comparison of piloted-system frequency response for various quadratic weighting factors. The basic equations for transfer function analysis are presented here.

### Transfer Functions from State-Vector Equations

It is readily shown, e.g., Gilbert,<sup>33</sup> that for a state-vector system

$$\begin{aligned}\dot{x} &= Ax + Bu \\ y &= Cx\end{aligned}\tag{C-1}$$

the transfer function  $T(s) = Y(s)/U(s)$  is

$$T(s) = C(sI-A)^{-1}B\tag{C-2}$$

By expanding  $(sI-A)^{-1}$  as shown by Gantmacher<sup>34</sup> this becomes

$$T(s) = C[q(s)]^{-1}[P_1s^{n-1} + P_2s^{n-2} + \dots + P_n]\tag{C-3}$$

where the characteristic polynomial is

$$q(s) = \det(sI-A) = q_1 s^n + q_2 s^{n-1} + \dots + q_{n+1} \quad (C-4)$$

and the numerator polynomial coefficient matrices are given by the recursive relations

$$\begin{aligned} P_1 &= q_1 B = B, & q_1 &= 1 \\ P_i &= AP_{i-1} + q_i B, & i &= 2, 3, \dots, n \end{aligned} \quad (C-5)$$

This can be expanded to more complicated systems for theoretical purposes, e.g., Gilbert.<sup>35</sup> However, the systems considered in this study could be reduced to this simple form for numerical calculations.

The computer algorithm for transfer function calculations presents no problems in concept. In outline it involves

- (1) formation of the system matrices of Equation (C-1),
- (2) calculation of the eigenvalues and the characteristic polynomial coefficients of Equation (C-4) using a suitable eigenvalue or characteristic polynomial routine,
- (3) formation of the numerator polynomial coefficient matrices of Equation (C-5),
- (4) calculation of numerator roots, and
- (5) cancellation of equal factors in the numerators and denominators of each transfer function.

In practice, the algorithm was difficult to apply numerically. Highly accurate CDC 6600 double precision routines were required for the eigenvalue, polynomial root, and polynomial multiplication calculations. The programs were used

successfully on systems up to 25th order and for some systems involving low gain partial state feedback of a large number of states. However, when possible, any decoupled state equations were removed from Equations (C-1) before application of the algorithm in order to increase accuracy.

A check on the accuracy of the numerical calculations for the algorithm is provided if we note that continuing to  $i = n+1$  in Equation (C-5) we obtain  $P_{n+1} = AP_n + q_{n+1}B$ . This can be expanded by repeated substitution according to Equation (C-5) to obtain

$$P_{n+1} = (A^n + q_2A^{n-1} + q_3A^{n-2} + \dots + q_{n+1}I)B \quad (C-6)$$

But from the Cayley-Hamilton Theorem we know that the matrix,  $A$ , satisfies its own characteristic equation; thus,  $P_{n+1}$  should be identically the zero matrix. In practice, the transfer functions in this study were computed successfully even though occasionally some terms in  $P_{n+1}$  were relatively large due to error accumulation. Accuracy of the eigenvalue calculation can be improved by careful scaling of the equations in the system when possible.

### Transfer Function Formulation for Pilot Model Analysis

In order to calculate the pilot open loop transfer function for the flight director loop closures the loops were opened at the pilot control vector junctions. The piloted system equations, Equation (II-73), neglecting the disturbance terms, and Equation (II-75), could then be used for

pilot loop analysis. We note that these are in the form of Equation (C-1); thus, from Equation (C-3) we obtain immediately  $T(s) = Y(s)/U(s)$ . Then, the pilot open loop transfer function  $[U(s)/U(s)]_{OL}$  is obtained from Equations (II-5) and (II-77) as

$$[U(s)/U(s)]_{OL} = -HT(s) \quad (C-7)$$

To obtain only the pitch and roll loop closures the gains  $K_{d_z}$ ,  $K_\psi$ , and  $K_{d_y}$  were equated to zero in the observation matrix, Equations (II-76).

One must note that frequency domain flight director design using the procedures of Reference 17 can not be accomplished in the exact same manner for the system in this study. In Reference 17 the pilot lead equalization was applied only to the pitch and roll flight director feedback terms. In this study the lead equalization was applied to all flight director error command components. Thus, attempting to open each of the altitude, yaw, or lateral error loops at the flight director summing point would actually open two loops, the magnitude and rate loops, simultaneously, and at the pilot control input junction, not the flight director summing junction as in Reference 17.

## Appendix D Main Computer Programs

This extensive study made use of several major computer programs for the optimal control problems, the frequency analysis transfer function calculation, Bode plotting, root locus plotting, and validation of the system equations. Smaller programs were also required to mechanize the data handling and prepare the final data listings and plots. Several of these programs have already been documented,<sup>21, 32, 36</sup> and the remainder will be documented by this author.<sup>37</sup>

For the purposes of this thesis it was desirable to list the main computer programs which were coded for this analysis to generate the system equations and to calculate the SAS design rate model. In addition, the main decks from the Heath optimal control program<sup>21</sup> which were modified to do the SAS design for this study are listed. These listings provide an additional verification of the actual equations and numerical data for the reader who wishes to check the details of this study.

The majority of the computations in this study was performed on the CDC 6600/Cyber 74 computers using the remote interactive INTERCOM system at the Air Force Flight Dynamics Laboratory. In order to efficiently handle all of the

# *Contrails*

execution on this interactive system the programs were organized in OVERLAY form. One set of OVERLAY programs was used principally for generating the system equations and other related tasks. The following subroutines from this program are listed here: MAIN00, MAIN10, ACDATA, TRIMUP, GUSMOD, EOM, FDPILLOT, and FEEDBAK. Another set of OVERLAY decks was used for the rate model calculation and SAS design. Subroutines from this OVERLAY program include the SAS design decks: INCFB, MDKT, and PMIN. The rate model terms were calculated separately for the longitudinal and lateral-directional modes using the decks: MODEL, FUNCT(L) and MODEL, FUNCT(LD). The symbols in the parentheses were added to identify each deck in the CDC UPDATE program library.
